The stressful situations whose effects were discussed were various. Professor SELYE described the effects of immobilization on cats in terms of adrenocortical mechanisms and the general adaptation syndrome. Dr. H. HOAGLAND, of the Worcester Foundation for Experimental Biology, discussed the effects of situations allowing no outlets for aggression on the excretion of adrenaline, noradrenaline, aldosterone, and related compounds by sportsmen, patients, and others. Professor H. S. LIDDELL (Behaviour Farm Laboratory, Cornell University) discussed the part played by restraint in the Pavlov harness and frame in the production of experimental neurosis in pigs, sheep, and goats. Dr. E. J. ANTHONY (Institute of Psychiatry, London) reported on the part played by restrictive and coercive attitudes of mothers in the production of sleep disturbance and encopresis in children. These situations have in common that the organism is restrained or confined, and the restraint prevents or imposes delay on adaptation. Superficially, although perhaps not fundamentally, they differ from the other psychosocial stressors discussed.

Professor E. LINDEMANN, of Harvard University Medical School, described the effects on the health of adults of bereavement—that is, what he termed "the cessation of interaction with an emotionally relevant person." Professor interaction with an emotionally relevant person." Professor M. ROTH (Durham University) reported similar effects in the elderly, and Dr. JOHN BOWLBY (Tavistock Clinic, London) pointed out the similarities in the concept of bereavement and his own concept of the effects on the young child of separation from the mother. Brigadier R. PHILLIPSON, director of Army psychiatry, reported on the effects reflected in official sickness statistics of removing young men from their families for the two-year period of National Service. Mr. E. L. TRIST (Tavistock Institute of Human Relations, London) discussed the effects of the reorganization of working groups on the sickness-absence, accidentation, and productivity of coal-face workers. Professor H. G. WOLFF, of the New York Hospital, reported data which show that disturbances in social relationships perceived by individuals as threatening are correlated with increases in the incidence of a wide range of diseases, many of them not hitherto regarded as "psychosomatic" (such as bronchial carcinoma). Professor LIDDELL reported that kids which have been separated from their dams for an hour or two immediately after birth suffer a very high mortality subsequently, the majority dying within a year. All these psychosocial stressors demand from the individual a "role transition" and a reorganization of social relationships, which may be successfully accomplished; otherwise illness and even death result.

Conflict and Monotony

This does not exhaust the list of stressful situations discussed. Dr. R. A. HINDE (Cambridge University) described the several different classes of behaviour observed in birds when they are subjected to conflicting stimuli to behave in incompatible ways or when they suffer deprivation. Professor LIDDELL told how the presence of the mother reduces the effects on lambs of monotonous, unreinforced stimulation. Lambs so tested in the presence of their mothers move freely and actively about the pen; lambs separated from their mothers become virtually immobile.

The attempt was made by several speakers to identify the common features in all these situations. Stressful situations, it was remarked, are those in which drives remain unsatisfied, or expectations are not fulfilled; there is a mismatch between the actual and the target (the "is" and the "ought-to-be"), business is unfinished, problems are not resolved, or there is a crisis—that is, suspense in the taking of a decision. Perhaps all these definitions amount to much the same thing.

The stress-strain analogy from physics is unsatisfactory in at least one important respect, it was agreed, when the effects of stress on organisms are considered. The effects constituting strain in materials cease as soon as the stress ceases, whereas the agents or situations which cause strain in the adaptation mechanisms, even if they produce disorganization, tend also to produce reorganization, which is not reversed. Great importance was attached by several speakers to the processes of reorganization, whether they described these as "reprogramming," "the establishment of new defences," or "the redistribution of interactional patterns"—for example, following bereavement. Dr. DENIS HILL (Institute of Psychiatry, London), in an interim summing up, defined stress as a "process of change during which a new adaptation may be reached."

Fixity of Response Under Stress

There appears to be a general tendency for the reorganizations which result from stress to involve a narrowing, or stenosis, in the range of activities of the organism. A striking instance of such restriction in activities and interests is seen in the traumatic neuroses, and especially in the selective forgetting, or repression, which may follow upon stress. Reorganization in a given case may be evaluated by reference to the number and range of factors which the subject is able to take into account in making decisions. It is worth noting that each role-transition undergone by human beings as they grow up in a complex society tends to bring with it an increase in the specialization of their skills and interests.

Reorganization represents an at least partially successful adaptation to stress. Before it is accomplished, however, manifold changes in mental activity, behaviour, and physiological functions may be observed which reflect the homeostatic mechanisms and may be regarded as attempts at adaptation and restoration or reorganization. Psychological observations suggest that stressful situations tend to produce immediately a narrowing of attention, or preoccupation, with a corresponding neglect of things that are peripheral in place or significance. At the same time as perception is thus affected, behaviour tends to become less versatile and more restricted and stereotyped. Another aspect of this tendency is the fixation of responses, which is a characteristic result of stress; particular responses tend to be repeated even after they have proved ineffective in relieving the stress. Thus the effects of stress on behaviour are selective. It is tempting to suppose that the uneven distribution of the effects of stress upon physiological and especially endocrinological functions reflects a similar tendency.

Dr. J. I. LACEY (the Fels Research Institute for the Study of Human Development, Yellow Springs), in particular, emphasized that the strain is always distributed unevenly; there is overaction of some mechanisms and underaction of others. He reported evidence to show that specialization and stereotypy in the responses of the autonomic nervous system to stress occur at least as early as 6 years old—that is, organ-vulnerability is established by this age. He asserted that the differential distribution of the effects shows some consistency over years and is largely independent of the nature of the stress. He attached major importance, therefore, to the constitutional determinants.

Professor SELYE pointed out, however, that the pattern of the stress responses composing the general adaptation syndrome varies widely with the conditions that are established experimentally, and Dr. HOAGLAND's results also show that the adrenal medulla's pattern of responses depends largely upon the nature of the stressful situation. There is probably some truth in both views.

EAST AFRICAN PHYSICIANS

The following are some of the points brought out at the annual conference of the Association of Physicians of East Africa, which was held in Nairobi from June 26 to 23 under the chairmanship of Dr. A. D. CHARTERS.

Tuberculous pericarditis is common in East Africa, according to Dr. P. P. TURNER, and often fatal. In about a third of the cases he could culture tubercle bacilli from the pericardial fluid. He recommended treatment with anti-tuberculous drugs, prednisone, and intrapericardial hydrocortisone. Although this might save life, the end result was poor and surgery might be needed. Dr. A. A. KHAN described 28 cases of radiologically proved duodenal ulcer in Africans admitted to the King George VI Hospital, Nairobi, between September, 1957, and April, 1958. Statistically, duodenal ulcer was on the rise in Africans in Kenya, and it affected all income, social, and educational groups. Dr. Khan thought it would become yet more frequent as urbanization of the African progressed. Dr. A. G. SHAPER said that steatorrhoea, on the other hand, was excessively rare in Africans. He described two cases.

Dr. J. M. VAIZEY illustrated the change chloramphenicol has made in the outlook for the typhoid patient by comparing the results achieved at Mulago Hospital in 1957 with those in 1949, when chloramphenicol was not available. Mortality had fallen from 24.5 to 7.5%, and the duration of fever and of stay in hospital by about a half. The complications of haemorrhage and perforation still remained serious, however. Dr. Vaizey also reported the emergence of a resistant strain of *Salmonella typhi*. Dr. K. SOMERS described the severe iron-deficiency anaemia which often occurs with heavy hookworm infections in Uganda and sometimes leads to heart failure. He demonstrated the reversible E.C.G. changes found in 15 such patients.

Dr. P. MANSON-BAHR read a paper on histoplasmosis in East Africa. All forms of the disease had been reported there—the localized, the disseminated, and the benign pulmonary form. Dr. Manson-Bahr then described a case of benign pulmonary histoplasmosis (or "cave disease") in a European male who had visited the Amboni caves near Tanga (Tanganyika), where the floor is covered in bat guano. Symptoms developed 14 days later and a histoplasmin skin test was positive. Treatment did not help, but the patient made a gradual spontaneous recovery.

To-day's Drugs

In this column we publish from time to time authoritative notes on a selection of drugs in current use.

Apresoline (Ciba Laboratories Ltd.).—This is 1-hydrazino-phthalazine hydrochloride, or hydralazine, in tablets of 25 mg. or ampoules containing 20 mg./ml. Hydralazine lowers arterial blood pressure by producing generalized vasodilatation. In addition to reduction of blood pressure, cardiac output and renal blood flow are increased. The glomerular filtration rate remains unchanged or falls as a result of glomerular arteriolar dilatation. After intravenous injection, the arterial pressure begins to fall within 20 minutes, reaches its lowest level between 20 and 90 minutes, and returns slowly to pre-injections level in 4–8 hours. The cardiogram may show transient ST depression and T wave inversion,

especially in subjects with hypertensive or ischaemic heart disease, probably as a result of increase in cardiac output without increase in coronary artery flow.

Hydralazine can also reduce arterial pressure when given by mouth, but side-effects may be prominent, consisting of headache, flushing, palpitations, oedema, nausea, and vomiting. In about 10% of subjects a syndrome resembling systemic lupus erythematosus appears after 4–8 weeks' treatment and necessitates withdrawal of the drug.

The side-effects of the drug limit its value, while the effect on cardiac output prohibits its use in patients with hypertensive or ischaemic heart disease. It is usually less satisfactory than the ganglion-blocking agents, but has been used in combination with hexamethonium or reserpine. It may occasionally have a place in the treatment of patients with hypertension and renal failure in whom the reduction in renal blood flow produced by ganglion-blocking agents is undesirable. It is advisable to start treatment with small doses and increase gradually. In late pregnancy, the free passage of ganglion-blocking agents across the placenta may cause dangerous ganglion blockade in the foetus, and in these circumstances a limited course of hydralazine by mouth, or in emergency by injection, may be warranted if reduction in blood pressure is required.

N.H.S. basic price: 100 25-mg. tabs., 11s.; 100 50-mg. tabs., 20s. 4d.; 6 ampoules, 10s.

Predsol Nasal Drops (Glaxo Laboratories Ltd.).—Prednisolone disodium phosphate 0.1% in isotonic buffered solution.

Predsol-N Nasal Spray (Glaxo Laboratories Ltd.).—Prednisolone disodium phosphate 0.025%, neomycin sulphate 0.5%, and naphazoline nitrate 0.025% in aqueous solution.

Delta-Feno Nasal Spray (Boots Pure Drug Co., Ltd.).—Prednisolone 0.01%, phenylephrine hydrochloride 0.25%, naphazoline nitrate 0.025% in an aqueous solution.

This is a series of preparations of prednisolone for local application to the nose for hay-fever and vasomotor rhinitis. Provided the presence of serious infective conditions such as sinusitis can be excluded, there seems no objection to their use. They provide an alternative to hydrocortisone snuffs, and seem to be equally satisfactory and rather easier to use. Predsol, which contains only prednisolone, would seem likely to be the most satisfactory preparation, but no doubt the combination with neomycin is unobjectionable for local application to an infected allergic mucosa.

N.H.S. basic price: Predsol nasal drops, 10 ml., 5s.; predsol-N nasal spray, 15 ml., 5s.; delta-feno nasal spray, 15 ml., 3s.

Hibitane Dihydrochloride (Imperial Chemical Industries Ltd.).—This compound, chlorhexidine dihydrochloride, is a slightly soluble white powder which is strongly bactericidal against a wide range of micro-organisms, including staphylococci, streptococci, and coliform bacilli. It can be sterilized by dry heat at 150° C. for one hour. Resistant strains are not found and do not emerge in attempts at habituation. Its activity is somewhat diminished by contact with serum and blood.

Because of its bactericidal properties and low solubility, chlorhexidine dihydrochloride has been found suitable and safe as an application to burns, with some prophylactic action especially against *Staph. aureus*. It is desirable to use it in combination with other agents, such as neomycin and polymyxin. The cream should be made with a non-ionic emulsifying wax (e.g., cetomacrogol B.P.C.) and contain 1 or 2 mg. "hibitane" dihydrochloride per gramme of cream. It is unlikely to be of therapeutic benefit in cases of established infection. Wound-dusting powders (5% with lactose) have also been used. For other uses of chlorhexidine, such as disinfection of skin and of instruments, the soluble chlorhexidine diacetate is more suitable.

N.H.S. basic price: 10 g., 7s.

Correspondence

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Tabo-paresis

SIR,—Some senior and experienced psychiatrists have recently had cause to give considerable thought to the topic of tabo-paresis. One British psychiatrist recently found that there was concern in responsible circles in America on the same topic. When the time-lag between primary infection with syphilis and the onset of tabo-paresis is considered, it appears possible that the recent virtual disappearance of tabo-paresis is due to the efficiency of arsenical treatment in the years before the large-scale employment of antibiotics.

It may be that cases treated in the early years of the antibiotic era have yet to develop tabo-paresis. The time factor suggests that the next few years may be particularly important in this respect. Recently a senior psychiatrist with considerable experience of neurosyphilis had four cases referred to him within a very short period—more cases than he had seen for a very long time previously. Two of these cases could easily have been missed by a more junior man with little practical experience of tabo-paresis. Moreover, some of the old, characteristic physical signs seem to be changing somewhat.

It may be hoped that fears of a reappearance of tabo-paresis on a considerable scale may prove groundless, but there appears to be reason for clinicians to be very alert on this topic, so that if an increase in the number of cases should occur the sufferers from it may be diagnosed early and therefore successfully treated.—I am, etc.,

NOEL G. HARRIS,
Chairman, Public Relations Committee,
Royal Medico-Psychological Association.

Neurological Complications of Pertussis Immunization

SIR,—Drs. D. C. Thursby-Pelham and C. Giles's letter (*Journal*, July 26, p. 246) is of great interest. It is remarkable that Dr. Thursby-Pelham has seen six patients in the space of 10 years with neurological reactions following pertussis immunization, in view of the fact that only seven such cases have been recorded in Great Britain (see my paper, *Journal*, July 5, p. 24). One of these seven is Case 2 in their series. It may be, as Drs. Thursby-Pelham and Giles state, that the dangers of whooping-cough immunization are greater than is commonly thought, but this can only be established if the possibility of reactions to immunization are borne in mind and reported when they occur. One would like to make a plea, therefore, that this should be done.

It is possible that the relatively large number of cases of neurological complications of pertussis immunization reported from the United States, as opposed to other countries, including Britain, is due to a greater awareness of, and interest in, the problem in America. If further cases are reported, as Drs. Thursby-Pelham and Giles have now done, it may be that the commonly held view, that the dangers from whooping-cough itself are much greater than those from immunizing against it, will require modification.—I am, etc.,

J. M. BERG.

London, S.W.17.

SIR,—Further to the article by Dr. J. M. Berg (*Journal*, July 5, p. 24) and the letter from Dr. D. C. Thursby-Pelham and Dr. C. Giles (*Journal*, July 26, p. 246), I have given many thousands of injections of both combined diphtheria-pertussis and triple antigen vaccines, and in two instances only have I known convulsions to follow, in sisters.

Case No. 1.—A female infant, first child of a Rhesus-negative mother. Became jaundiced three days after birth. Was admitted to hospital but replacement transfusion unnecessary. At 6 months of age she had a severe convulsion which occurred four hours after her first injection of triple antigen. She was un-

conscious for 10 minutes and made a full recovery within 24 hours. One month later she had a similar convulsion following her second injection. The third dose was not given and one year later she was seen and is quite normal.

Case No. 2.—Sister of Case No. 1. Female infant. Second child of a Rhesus-negative mother. Labour was induced at 38 weeks. At birth, the infant was severely affected by haemolytic disease and replacement transfusion was carried out. At 4 months of age the first injection of triple antigen was given. Three hours later a minor convulsion occurred. Recovery was complete within a short while. In view of her sister's reaction after her second injection, and after reading the article by Dr. Berg, no further injections were attempted.

The fact that these two cases were sisters both suffering at birth from haemolytic disease and both born of a Rhesus-negative mother makes me wonder if the aetiology of this dangerous reaction to pertussis vaccine may not in some way be connected with the Rhesus factor.—I am, etc.,

Tetbury, Glos.

JOHN N. H. ANDREWS.

Dummy Tablets

SIR,—Dr. E. C. Atkinson (*Journal*, June 21, p. 1478) makes out a case for having "some control tablets of inert substances" or "a genuine placebo" included in the *British National Formulary* to help doctors with their investigation of "the relative values of the mass of proprietary drugs" which appear on the market. Dr. W. N. Leak (*Journal*, June 28, p. 1546) points to the difficulty which may arise for a doctor prescribing dummy tablets, when he has to choose between honesty with his patient and impersonal science; and concludes "regrettably, that it would be wrong for the B.N.F. to include a dummy tablet. . . ." May I set out in detail some of the considerations which should guide a family doctor in his choice of controls for any therapeutic research which he intends to pursue?

It is not primarily the task of a family doctor to test the pharmacological effects of unknown or untested substances on those who seek his advice about their treatment. Logically a doctor could only advise a patient to take such an unknown substance if there was no accredited or orthodox treatment for the condition from which he was suffering. The medicaments prescribed by a general practitioner should be those which he uses in good faith and on the basis of knowledge which he has obtained of their composition and action from different sources. Where the progress of a disease invariably follows a predictable and well-established course, then the past experience of accumulated medical knowledge supplies the control for any therapeutic trial of a possibly beneficial drug, and no other may be needed. The most obvious examples are those diseases in which death is the invariable or predictable result. If, on the grounds of a reasonable hypothesis, the first therapeutic trial of a new substance for the treatment of such a disease were being planned—for example, streptomycin in tuberculous meningitis—it could be argued that it would be unethical to withhold this test substance from any patient in the trial. A proper structure of this first trial might well be to test the action of the new substance in a continuous series of cases until the question was beyond doubt, either that it had no action or that the predictable course of the disease was undoubtedly altered by the use of the test substance. In general practice, however, such trials are rare.

Therapeutic research in general practice falls broadly into six categories. The first, and perhaps a neglected field, is a fresh assessment of the action of time-honoured remedies in common diseases—for example, the use of potassium iodide or tincture of stramonium in asthma. Second comes the controlled trial of new drugs for old and familiar diseases, such as the prophylactic use of sulphonamides for the complications of measles. Third come trials designed to reveal new uses of familiar drugs, such as aspirin in diabetes. Fourth, and we hope rarely in general practice, comes the administration of new and unfamiliar drugs to patients with diseases for which a standard treatment already exists. The fifth comprises those trials where the family doctor is in ignorance of the precise nature of the

substance which he personally prescribes or dispenses for any particular patient—for example, "blind" trials—and, lastly, there is the experimental use of drugs in volunteers who may be either sick or healthy.

In planning a therapeutic trial of any of the first three types, if a control is necessary, what kind should be selected in general practice? There are four possibilities: (i) the action of the drug in question may be compared with that of one or more other accredited remedies already in common use for that particular disability (e.g., potassium iodide or tincture of stramonium in asthma; sulpha drugs or penicillin in measles); (ii) the action of the test substance may be compared with that of one or more *innocuous* substances or mixtures, whose accepted use in general practice lies as much in their psychological as in their chemical value, in so far as they have been found to allay any apprehension by the patient that nothing could be done for his condition (placebo); (iii) the action of the test substance may be compared with that of one or more "inert" substances; strictly speaking these should have been proved already to have absolutely no positive or negative action on the course of the disability for which they are given, but more commonly the phrase is used to include substances which are *expected to be inert* but whose action in this disability has never been put to a critical therapeutic trial. Where an "inert" substance is made to resemble in presentation the form of the test substance, the use of the phrase "dummy" tablet (mixture, capsule, etc.) is not only justified but more explicit, since it draws attention to the purpose of the counterfeit, which is to deceive the patient and often also the doctor taking part. (iv) The action of giving the test substance may be compared with that of withholding it. In fact this is what is done in both (ii) and (iii) above, and the reasons for choosing either (ii) or (iii) rather than (iv), or for choosing (iii) rather than (ii) needs to be examined closely.

In trials of the fourth, fifth, and sixth types mentioned above—namely, with unfamiliar drugs—if the general practitioner is working "blind" or where the consent of the patient is sought, legal and ethical as well as statistical difficulties may arise for the investigator. For example, it is the duty of a doctor to act only in what he considers to be the best interest of each individual patient. He ought not, in relation to any particular patient, to regulate his treatment according to any other consideration unless with the express knowledge and approval of his patient. An "infant" cannot and his parents may not give consent for any treatment not directed towards his own benefit; he may not be experimented on for the sake of others. Furthermore, it is dangerous to rely merely on the knowledge and approval of the patient, because he does not have the necessary medical knowledge to enable him to appreciate in full the considerations involved; the doctor would have to be quite sure that the patient really had a full appreciation of the position. This is particularly important when the toxicity of the trial substance is uncertain or known not to be negligible. Failure to act in accordance with the principles set out above might expose the doctor to risk of legal proceedings, based on a breach of contract or duty, or on assault.

Any general practitioner taking part in the National Health Service has a further duty to carry out his terms of service conscientiously and to the best of his ability. In selecting an inert substance as the only treatment of a patient seeking medical advice, the legal requirements of the terms of service under the N.H.S. would seldom, if ever, be met.

In dealing with new drugs a clear distinction should be drawn between a general practitioner's use of an unfamiliar drug on the advice of a consultant, as the appropriate and necessary remedy for a particular patient, and his use (either alone or with others) of a drug with which he is unfamiliar or uncertain, as part of a clinical trial on patients, whether volunteers or not. It is one thing to use a familiar drug as a new line of treatment in some particular condition; it is quite another to experiment with new drugs on our patients as though they were guinea-pigs.

Finally a word about "blind trials," in which the person observing the response to treatment is intentionally kept in ignorance of whether a particular patient is receiving the trial drug or a control. Such an observer is really acting

as an assistant to those who planned the trial. A family doctor who is in general practice as a principal could ethically be in some difficulties about taking part in such a trial, unless he had a share in its design, since he is personally responsible to his patients for the treatment which he prescribes for them. An assistant, however, can act as observer for his principal, and a single-handed practitioner can plan his own "blind" trials, if he in turn seeks help from a nurse or relative as observers, or in appropriate cases from the patient himself. This applies particularly to trials in which treatment is given for the relief of symptoms, such as pain, sleeplessness, worry, or anxiety, rather than for the alteration of physical signs which the doctor himself can observe. For all these reasons I agree with Dr. Leak, without regret, "that it would be wrong for the B.N.F. to include a dummy tablet. . . ."—I am, etc.,

Peaslake.

G. I. WATSON.

Congenital Dislocation of the Hip

SIR,—In your annotation on congenital dislocation of the hip (*Journal*, July 5, p. 38), you say that most cases of the disease in this country are diagnosed at the age of 1 or 2 years. A recent answer in "Any Questions?" referred to asymmetry of the skin creases as a useful sign.¹ Much earlier diagnosis could and should be made. Professor Marino Ortolani,² director of the Instituto Provinciale per l'Infanzia, Ferrar, has described a sign which can be elicited in newborn babies which is obviously not sufficiently well known in this country. First the thigh is flexed on the abdomen; then pressure is exerted along the long axis of the femur. The femur is then abducted. As the head of the femur rolls over the rim of the acetabulum there is a click, which may be felt or even heard.

From now on all newborn babies should be subjected to this manoeuvre at their first examination. In this way cases will be detected early, and much suffering prevented.—I am, etc.,

Bath.

Aetiology of Cancer

SIR,—The highly interesting lecture on the aetiology of cancer by Dr. Ludwik Gross (*Journal*, July 5, p. 1) prompts me to draw some conclusions from the viewpoint of a clinician. The principle of "vertical transmission of potentially pathogenic agents" remaining harmless to their hosts often for generations and activated into cancer-producing pathogens only occasionally by "obscure reasons," "intrinsic or extrinsic stimuli," necessitates the following unavoidable logical conclusion as to human cancer aetiology. The latent harmless pathogenic agent must be ubiquitous in humans, since there is hardly any human family without a case of malignancy in the last four or more generations. In other words, every human being would be potentially susceptible to malignancy and the real enigma of cancer aetiology would remain unsolved because "the obscure reasons" for activation of the cancerogenic virus would be completely unknown in the great majority of human cancers.

We must taken exception to Dr. Gross's statement that genetic factors as contrasted with "vertical transmission" are "transmitted in an orderly and foreseeable manner." This is not the case where polygenic (multifactorial) heredity is involved.¹ As to inheritability of predisposition to malignancy, it can be foreseen as little as physical resemblance of a child *in statu nascendi* to any of his ancestors. Thus the genetic concept of cancer aetiology does not seem to me to be overthrown by the concept of "vertical transmission" of a virus. The question of similarity of a gene with a virus, however, is another matter.—I am, etc.,

Childhood Malignancies

SIR,—I have read with great interest the paper of Dr. Alice Stewart and her colleagues entitled "A Survey of Childhood Malignancies" (*Journal*, June 28, p. 1495). If diagnostic x-rays can cause leukaemia, it is reasonable to assume that they can also cause non-malignant changes of importance in the leucopoietic tissues. It is known that toxic substances like benzol which can cause leucopenia can also cause leukaemia. It would be interesting to know whether diagnostic x-rays can, in childhood, cause leucopenia, however slight, especially after radiographs which have been taken in pregnancy.

The dose concerned in radiodiagnosis is very small, and the radiation which penetrates the bone and reaches the bone marrow is only about 10% of the surface dose. The reticulo-endothelial apparatus on the other hand receives the full surface dose over the entire body. This radiation could easily be significant in a foetus of which a radiograph is taken during pregnancy. According to Dominici,¹ even myeloid cells can originate in the reticulo-endothelial apparatus, as I was able to confirm.² Non-malignant changes in the leucopoietic system, caused by x rays, are usually eliminated by recovery, but can lead, if permanent leucopenia ensues, to leukaemia or impairment of cellular and humoral reaction.³ In order to avoid the exposure of the entire radio-sensitive foetal reticulo-endothelial apparatus to radiation, radiographs should be avoided during pregnancy, if not strictly indicated.—I am, etc.,

F. FRIEND.

Comfort in the Surgical Ward

SIR,—Your leading article entitled "Comfort in the Surgical Ward" (*Journal*, July 12, p. 95) prompts me to make a few comments and a practical suggestion regarding post-operative thrombo-embolic phenomena. These "complications" still occur in spite of (and as you mention) early plications, since the process has commenced *before* the ambulation, since the process has commenced *before* the patient has recovered consciousness and is fit to carry out the various exercises, etc., advised. There are other factors—the indolent patient, changes in the constituents of the blood, etc.

Why is it that the thyrotoxic patient so very rarely suffers from thrombosis and embolism? In the few hundred thyrotoxic cases I have operated on I cannot recall a single case of thrombosis or embolism. The absence in the thyrotoxic of these phenomena—so distressing and dangerous—may be due to the faster circulation time, high B.M.R., increased hyperkinetic movements in bed, a lowered blood cholesterol level, etc., all of which should be considered and assessed. This freedom from thrombosis, etc., occurs whether the operation on the thyrotoxic patient is in the neck or in another region. As a practical suggestion I submit that, as a prophylactic, we should make patients somewhat thyrotoxic *before* operation. Here again the risks would have to be considered.—I am, etc.,

Dundee.

F. R. BROWN.

Card for Patients on Steroid Therapy

SIR,—It is recognized that sudden withdrawal of steroids in patients undergoing long-term treatment may be dangerous, particularly when such patients have been subjected to sudden stress, such as an acute illness, accident, or emergency operation. In these circumstances it may be of vital importance for the physician or surgeon responsible for the patient's immediate care to be made aware that the patient has been on steroid therapy, the form in which it is being administered, and the daily dose.

The education subcommittee of the Empire Rheumatism Council gave this matter consideration at a recent meeting

and reached the conclusion that a useful purpose would be served by the issue of a card (see Fig.) to patients receiving steroids, stating the preparation in use and its daily dose. The hospital or clinic supervising the patient's treatment and the name and telephone number of the family doctor should

STEROID TREATMENT

Hospital:	
Name:	
Address:	
Family Doctor	Phone No.
Drug	
Date	
Daily Dose	

1. DO NOT STOP taking these tablets except on medical advice. Always have a supply in reserve.
2. In case of acute illness, accident or emergency operation the treatment MUST be continued. A LARGER dose may be necessary at such times.
3. If the tablets cause indigestion, consult your doctor AT ONCE.
4. ALWAYS CARRY THIS CARD.

Issued by the:

EMPIRE RHEUMATISM COUNCIL
Faraday House,

Post-operative Pulmonary Function

SIR,—In their paper on the effect of abdominal operations on total lung capacity and its subdivisions (*Journal*, July 12, p. 84), Mr. Anthony R. Anscombe and Dr. Roger St. J. Buxton mention that they gave a bronchodilator (aminophylline) to two of their patients before and after partial gastrectomy and found no significant changes in the total lung capacity and its subdivisions. In 1950 I measured the maximum breathing capacity (M.B.C.) pre-operatively and post-operatively before and after the inhalation of 1 ml. of a bronchodilator (isoprenaline) in 12 patients undergoing elective repair of inguinal hernia. It was found that, whilst there was a reduction in M.B.C. after operation, there was no significant increase in the M.B.C. before or after operation after the bronchodilator in patients who had normal chests. In two patients with mild bronchitis, however (one of whom developed atelectasis), although there were trivial increases in the M.B.C. after the isoprenaline pre-operatively, post-operatively after the bronchodilator there were increases of 20% and 30%.

Subsequent experience with a large number of cases confirmed this suggestion that patients with slight and often unrecognized bronchitis are most likely to develop post-operative atelectasis when undergoing abdominal operations. The reason for this is that they readily develop bronchospasm and secrete viscous bronchial mucus, which in combination with the reduction in ventilatory capacity which occurs in all patients to some extent after abdominal operations, leads to sputum retention, atelectasis, and bronchopneumonia. These considerations led to the development of a regimen which was found to be very effective in the prevention and treatment of post-operative atelectasis.—I am, etc.,

Aberdeen.

Dysgerminoma in Pregnancy

SIR,—Dr. Jill M. Evans's report of a case of dysgerminoma in pregnancy (*Journal*, July 12, p. 105) was very interesting, but, without being captious, one may ask why a patient, 14 weeks pregnant, who had a "mobile firm swelling . . . the size of a foetal head," was discharged

from hospital and not subjected to laparotomy until four weeks later. It is surprising that so many textbooks still subscribe to the view that ovarian tumours should not be removed until after the 16th week of pregnancy because of the increased risk of abortion in the earlier months. Under modern conditions, however, the planned removal of pelvic tumours would appear to be far less dangerous to the foetus than the 10 to 20% abortion rates given by McKerron¹ and Spencer,² the usual authorities quoted, and any increased tendency to abortion would be more than outweighed by the technical advantages of operating in early pregnancy—ease of access, less handling of the uterus, etc.

In a paper read to the Newcastle Obstetric Society in May, 1954, I reported a series of 46 cases in which ovarian tumours and fibroids had been resected in early pregnancy with only one abortion resulting. (Most of the operations were performed by my former chief, Dr. Frank Burke, of Sunderland.) No fewer than 17 patients were dealt with during the first trimester, and in three of these an active corpus luteum was found in the cyst wall on section. During the past three years I have performed a further two myomectomies and excised five ovarian cysts before the 16th week without any foetal loss. Solid ovarian tumours are apt to be malignant (as in Dr. Evans's case), and by virtue of their weight and mobility there is a greater tendency to torsion. Hence I feel that the preferable policy for such cases is to operate as soon as possible without any reference to the duration of pregnancy.—I am, etc.,

J. P. O'DWYER.

Ballinasloe, Co. Galway.

Chromosomal Sex and Abnormal Sexual Development

SIR,—Since reporting upon an investigation into the oral smear method for the determination of chromosomal sex in a group of 260 normal individuals¹ we have had opportunity to apply the technique to more than 60 cases of abnormal physical or psychological sexual development. As was the case with normal individuals, we experienced little difficulty in determining the chromosomal sex from oral smears, and, provided the criteria which were stipulated in the previous study were observed, a count of 25 cells proved sufficient. With the younger cases, the youngest child being 1 month old, the examination was a little more tedious, for, as we also observed previously, it is difficult to find the appropriate number of suitable cells in a single smear. We would advocate therefore in these cases that as routine practice more than one smear should be available for examination.

The results from this further application of the oral smear technique emphasize our earlier contention that in the majority of cases skin biopsy for chromosomal sex determination appears to be unnecessary.

The present series includes cases of true and pseudo-hermaphrodites; Turner's and Klinefelter's syndromes; eunuchoids, transvestites, and homosexuals. The method has been particularly useful in separating out those cases with definite physical abnormalities—for example, Klinefelter's or Turner's syndrome—from those of an essentially psychological nature, without resort to laparotomy. In the psychologically maladjusted group it has been our invariable experience that the physical sex diagnosis is borne out by the chromosomal sex findings.

It has been most interesting to note that the incidence of sex chromatin in some of the chromosomal females with physical abnormalities has been surprisingly low, falling well below the normal incidence range¹; in a limited number of cases this feature has also been observed in the mother of the patient. However, at this stage we are unable to comment on the significance or otherwise of this finding. Finally we would agree with other workers^{2,3} that, whilst this method appears to give a true diagnosis of genetic sex, it

should not be allowed to exercise undue influence in the determination of the "social sex" of the individual.

We are much indebted to Professor R. Platt, P.R.C.P., of Manchester Royal Infirmary; Mr. L. R. Broster and Mr. J. Adler, of Charing Cross Hospital; and Drs. P. M. F. Bishop, F. Osmond-Clarke and M. Murray, of Chelsea Hospital for Women, for sending us material for investigation.

Suffocation in Infancy

SIR,—Dr. W. H. Davison (*Journal*, July 26, p. 248) is quite right to reply to Dr. J. Shackleton Bailey's letter (*Journal*, July 12, p. 104). Our own findings would go even further than those of Dr. Davison's survey in Birmingham. Even when the circumstances would appear to be greatly in favour of overlying, it is frequently possible to find an adequate natural cause of death. We are prepared to go so far as to suggest that the normal child is never simply "found dead in bed or cot from external mechanical suffocation."

I feel that it is important for the benefit of other children in the same family when a child is found unexpectedly dead that the parents should not be subjected to a police investigation. It is surely not necessary for a doctor to submit a child immediately to the coroner as a suspected case of suffocation if he can in the meanwhile obtain the parents' consent for necropsy, and have the body examined by a pathologist experienced with such cases. It is equally important that the parents should not be blamed for leaving a child on a pillow or taking it into bed with them.—I am, etc.,

Sheffield, 10.

JOHN L. EMERY.

Iron Preparations

SIR,—In Dr. C. F. Herridge's interesting paper on the comparison between ferric chelate and established iron preparations (*Journal*, July 19, p. 140), the question of cost is raised in assessing the choice for a given patient with iron-deficiency anaemia. The preliminary report of the Hinchliffe Committee has made many of us price-conscious, and therefore I have calculated the price of the three iron preparations, adding for comparison the B.N.F. mist. ferr. sulph. pro inf.

Dr. Herridge gave his three mixtures for six weeks, and I have calculated the total of each required to give his suggested dose. Some difficulty arose with the new ferric chelate mixture ("sytron"). The daily elemental iron (assuming a utilization factor of 14%) available from the dose he used is somewhat higher than the figure given. However, the commercially available sytron differs from the preparations available for Dr. Herridge's investigation in being only nearly half the strength (380 mg. per 8 ml. (approx. 2 drachms) instead of 600 mg.). I have therefore provided the price of 21 oz. (596 ml.) as suggested by Dr. Herridge, and of 27 oz. (767 ml.) as calculated to produce the daily figure of 142 mg. elemental iron. In the case of mist. ferr. sulph. pro inf. the quantity required to give the same daily amount of elemental iron (using the utilization factor of 14%) is 1.4 oz. (39.4 ml.) per day—a total amount of almost 60 oz. (1,704 ml.) for the six weeks. However,

Drug	Am't	Basic	P.T.	On-cost	C-A	D-F	Total
"Sytron"	27	200	60.5	65.125	1.55	48	375 (31s. 3d.)
"Ferlucon"	21	155.5	47	50.63	1.55	24	278.7 (23s. 3d.)
"Ferromyn"	10.5	75.5	Nil	18.88	1.55	14	109.93 (9s. 2d.)
Mist. ferr. sulph. pro inf.	8	94	28	30.5	1.55	14	168 (14s.)
	60	80	Nil	20	1.55	48	149.55 (12s. 5½d.)
	21	28	..	7	1.55	42	60.55 (5s. 1d.)

Am't: Quantity in fluid ounces (1 oz. = 28 ml.) calculated for six weeks.
Basic: Cost of ingredients or wholesale price. P.T.: Purchase tax. On-cost: An additional 25% of the basic price + purchase tax. C-A: Container allowance. D-F: Dispensing fee. Total: in pence.

clinical experience suggests that two drachms twice daily (9.5 oz. (14 ml.) per day, or a total of 21 oz. (596 ml.)), gives a satisfactory haematological response. I have therefore priced both 60 oz. (1,704 ml.) and 21 oz. (596 ml.) of the B.N.F. mixture.

The various factors which go into the price paid under the N.H.S. for a drug have been listed separately (in pence, as is the customary method). I find this breakdown of the total cost is as instructive as the cost itself. If any comment is to be made from all these figures it is that, while some preparations may have a valuable place in treating difficult cases (either difficult diseases or difficult patients), as "tonics" or placebos we should be very wary of their price.—I am, etc.,

London, W.12.

STUART CARNE.

Heat Illness

SIR,—Among the discoveries of Ur was a little clay image of the "God of the South Wind." Homer¹ mentions the death of one hero, during a battle before Troy, due to a "stroke from the Sun God" (translation by Andrew Lang). Alexander the Great (*O si sic omnia!*) chose the winter for his Mesopotamian campaign, culminating in the battle of Arbela on September 20, 331 B.C., attended by a lunar eclipse.

Your enlightened annotation and the article "A Classification of Heat Illness" (*Journal*, June 28, pp. 1351 and 1353) draw attention to a little-considered but very important problem. Clinically the "effects of heat" are numerous, and most extensively displayed by W. H. Willcox.² For practical purposes, hyperthermia (heat stroke) and heat exhaustion (heat collapse) may include all the major disorders: prickly heat and heat cramps being merely symptoms, although very unpleasant ones. The best and most universal form of treatment is the provision of an artificially cooled environment for the sufferers. Modes of prevention include suitable acclimatization, avoidance of drugs like atropine; anaesthetics are also taboo (unless in a cooled theatre); ichthyosis is an absolute bar to employment in the Persian littoral (gathered from bitter experience). For armies that have to consider shipping space a form of "iron lung" with mechanical refrigeration could be used to revive cases in the zone of operations. The Croonian Lectures by Dr. H. L. Marriott³ reveal a first-hand knowledge of the problems involved. He had to deal with conditions where no mechanical aid was possible: that phase should belong to the past. I have also made suggestions for improvement in hospital and living conditions and for better treatment.⁴ The writings of the late Professor M. S. Pembrey⁵ deal with the investigation of the problems of marching men. Endocrine factors are still much neglected—as remarked in your annotation, but the artificial production of "coolth" is still the keystone of the arch of treatment.—I am, etc.,

FRANK MARSH.

Prevention of Lung Cancer

SIR,—Whilst agreeing strongly with the ideas embodied in Dr. Lennox Johnston's letter (*Journal*, June 21, p. 1483) on the need for a national campaign to put the facts about smoking and lung cancer squarely before the public, he does, I think, miss one rather strong point. He omits the importance of directing such a campaign against children and young adults. The middle-aged man who has been smoking all his life is almost beyond redemption, but the children of to-day are the lung-cancer victims of thirty years hence, unless they can be taught the wisdom of not smoking. Young men in the Forces are also accessible to education in

this matter; my own Service days were punctuated by lectures and films on the dangers of venereal disease, malaria, and typhoid, so I should think that some education on the dangers of smoking would not be out of place.

Taken in its broadest aspect, the question of smoking and lung cancer has now entered the domain of preventive medicine, and as doctors we are neglecting our precepts and responsibilities if we do not say, "At last here is a positive approach in dealing with one major malignant disease, that of prevention." Which medical man in his right mind would fail to be shocked to learn that one of his patients was daily drinking tuberculous milk—particularly if this was a young person? And yet, year in and year out, every doctor has a large number of his patients paving their way to early and unpleasant deaths by a daily habit which is just as preventable as the marketing of tuberculous milk.—I am, etc.,

Boston, Lincs.

E. R. NYE.

Cancer Education

SIR,—I am sorry to have to take issue with so eminent a correspondent as Professor Ian Aird, but I feel most strongly that in his letter on cancer education (*Journal*, June 14, p. 1417) he has fallen a victim himself to the "education and propaganda" which he seeks to uphold. The term "cured of cancer" is probably more frequently used on this side of the Atlantic than Professor Aird's, and I am becoming more than ever convinced that its use is as much to satisfy the ego and present methods of the therapist—be he surgeon or radiologist—rather than to indicate the true status of the patient. After all, it rather depends on one's standards of "cure." If this only amounts to, say, one year's survival—to take an arbitrary figure—then a so-called cure is relatively easy to obtain, but if, on the other hand, 5, 10, 15, or 20 years of survival is demanded, then a cure becomes correspondingly more difficult to obtain. A cure can only be certain when a patient has received treatment for a carcinoma, and necropsy at some later time demonstrates that death is due to some other cause and that there is no evidence of the original carcinoma either macroscopically or microscopically.

I question the wisdom and truthfulness, in the present state of our knowledge, of instilling in the mind of the general public the idea that sometimes cancer, especially early cancer, is a curable disease. There is absolutely no proof to back up this statement. Absolute survival figures of treatment of carcinoma have altered little over the decades, and what improvement there has been is entirely due to the fact that blood transfusion, chemotherapy, antibiotics, and vastly improved anaesthesia have caused fewer patients to die from the immediate effects of treatment of the primary growth. Relative survival statistics are not worth the paper they are written on, as they are always "loaded" because the operator is choosing the most suitable cases for his particular type of therapy. By "early cancer" is meant a small circumscribed lesion, with no evidence of metastasis and a short or absent history. This could just as easily be an old carcinoma in terms of morphological time but one which is slow growing and slow to metastasize, which is the reason why it has not been picked up earlier. Obviously, treatment of such a lesion would lead to a reasonable survival time, but this is due rather to the nature of the carcinoma than the time at which treatment was given, as the lesion is a slowly growing and slowly metastasizing one.

Cancer detection clinics may have failed to improve the mortality from the disease, but they have contributed a great deal of useful data to our knowledge of the natural history of carcinoma. It now appears likely that a frankly carcinomatous epithelium may be restrained from spreading through the basement membrane and remain *in situ* for a variable time—sometimes for years. The epithelium may regress and return to normal, or it may progress to a frank carcinoma by the carcinomatous cells bursting through the basement membrane. The patient's fate is then decided by the metastasizing ability of the cells, and this occurs at a period of time long before a diagnosis is made. Again it is a question of standards when one discusses early carcinoma, and I do not think I need to labour the point further, except to point out that many doubtful carcinomas are being treated as carcinomas, with consequent vilification of statistics and subjection of patients to unnecessary surgery.

I have no objection to the public receiving cancer education as advocated by Professor Aird, provided it is based on truth, but can this be done at this time? May I draw the attention of your readers who are interested in this subject to two particularly informative and thoughtful articles which have probably been neglected because they do not subscribe to popular orthodox opinion, but which do indicate that perhaps a glimmer of truth is beginning to emerge from the morass in which we find ourselves. I refer to a paper by J. R. S. Douglas¹ entitled "Survival Curves as a Means of Investigating Cancer," and George Crile, junior's, paper "Factors Influencing the Spread of Cancer."²—I am, etc.,

Petersburg, Virginia, U.S.A.

Chloramphenicol Suspension for Intrathoracic Infections

SIR,—We would like to draw the attention of your readers to our experience with a suspension of 15% chloramphenicol for use as a local application in the treatment of certain intrathoracic infective conditions. We have used the suspension in six cases so far and have been favourably impressed with the results.

The series of six cases comprised five patients with pulmonary tuberculosis and one with a bronchial carcinoma. All six cases had surgical treatment carried out and developed their intrathoracic complications following operation. One of the tuberculous patients had a right upper lobe excision and developed a *Staph. aureus* empyema, and this responded to a course of systemic chloramphenicol combined with daily aspiration of the empyema space and the instillation of the suspension. In the other cases the infecting organism was a *Staph. aureus* too, but because of the nature of their condition and the operation performed it was difficult to eradicate completely the factors favouring continuation of their infection. Two of these were pneumonectomy cases who developed a *Staph. aureus* empyema of the pneumonectomy space, and although the suspension helped temporarily in overcoming the infection there was still a residual space left which would favour the perpetuation of chronic infection.

We feel it justifiable to publish these results, as in one case there was complete cure and in the other five cases definite clinical improvement was obtained. We feel, therefore, that the preparation described has a useful place to play in the local treatment of certain types of intrathoracic infections.

The 15% suspension was kindly supplied to us for clinical trial by Parke, Davis and Co., Ltd., through the kind auspices of Dr. H. W. Pearson

—We are, etc.,

JOHN G. STEVENSON.

Pioneers in India

SIR,—On reading the report of the opening of the Eighth Congress of the Medical Women's International Association (*Journal*, July 26, p. 244), I was surprised that the name of Dame Edith Brown was not mentioned among the pioneers in India. Dame Edith probably was the first woman doctor in India to receive this award. She founded the Women's Christian Medical College in Ludhiana, Punjab, about 1895. I am sure there are many, like me, who appreciated the loyal and trustworthy work done by the graduates of the Women's Christian Medical College, Ludhiana.—I am, etc.,

Cobham, Surrey.

HILDA L. KEANE.

Medical War Crimes

SIR,—My letter (*Journal*, July 5, p. 551) seems to have been so badly worded that I appeared to champion Dr. Herta Oberheuser. My intention was otherwise, and I would like to make this quite clear. I wished, in fact, to champion justice, which, I felt, might miscarry if we were ignorant of

the facts about her as she is now. This information was not presented.

I did not state that she was a "dedicated practitioner," only that she might be, which is a very different thing. There is not the slightest doubt in my mind about the enormity of her past behaviour, and for this very reason I thought it important to know something about her now. I felt that justice demanded such knowledge and that our verdict should have been tempered by it. However, it is obvious that, when the medical profession sits in judgment on its members, this particular principle is not observed.—I am, etc.,

Chesterfield, Derbyshire.

A. P. TAIT.

Orthopaedic Medicine

SIR,—I feel that the review by Professor J. H. Kellgren of the *Textbook of Orthopaedic Medicine* by Dr. James Cyriax (*Journal*, July 12, p. 93) should not be allowed to pass without comment. Some of the observations made are incredible. It is stated that "much of the treatment proposed seems to be of unproven value, since most of the complaints he is dealing with are naturally of short duration." Is it being suggested that a backache lasting several years is a complaint of short duration, and that, when it is dramatically relieved by manipulation, this contributes nothing to the immediate improvement? The sceptics may say that patients helped by manipulation are hysterics or neurotics, but in my opinion that is an admission of failure to explain the result, and every general practitioner knows that it is not a satisfactory explanation.

I do not know what is meant by the statement "the author shows a disregard for the dangers of spinal-cord lesions which have been so clearly demonstrated in recent neurological work and anatomical studies of the cervical spine," but I do know that I have given lasting relief to patients with backache and "fibrositis," by manipulation. I also know, after attending Dr. Cyriax's clinic, that the treatments carried out there are urgently needed in general practice and would result in a saving of thousands of pounds by removing these patients from the physiotherapy department, where they receive general physiotherapy of little or no value.

The material in the *Textbook of Orthopaedic Medicine* is based on years of experience in this work and thousands of cases successfully treated. The opinions given in the review are coloured too much by morbid anatomical studies, and I feel that the importance of careful clinical observation is not fully appreciated.—I am, etc.,

Hemyock, Devon.

THOS. LOGAN.

Electrified

SIR,—The other day, starting the septic hand clinic, I reached out to examine the first patient's hand, when, to my surprise and his, as our hands were about one inch (2.5 cm.) apart there was an audible snap. I experienced a sharp needle-like stab of pain in my thumb and the patient a similar stab in his index finger which made us both withdraw our hands involuntarily.

In many thousands of examinations I have never previously received a static electric shock, and so far as I could judge there was nothing peculiar about our clothing or the atmospheric conditions on this occasion. I wonder whether any of your readers have had similar experiences or can throw any light on the occurrence?—I am, etc.,

Birmingham, 4.

LIONEL H. PIMM.

POINTS FROM LETTERS

Fidgety Legs

Dr. PERCY G. HARRIS (Belfast) writes: "Orthoxine" (methoxyphenamine) is claimed by the makers as being effective for the relief of nocturnal leg cramp in old age and pregnancy. It occurred to me that patients complaining of "leg fidgets"—that most disturbing syndrome to the unhappy sufferer—might also benefit. In a small series this treatment has proved most effective, being almost 100% successful.

Obituary

W. E. BARNES, C.B.E., M.R.C.S., L.R.C.P., D.T.M.&H.

Air Vice-Marshal W. E. Barnes, formerly Deputy Director-General of Medical Services of the Royal Air Force, died at Brighton on July 28, four days after his 61st birthday.

William Edward Barnes was born at Finchley on July 24, 1897, and was educated at University College School, Hampstead. He interrupted his medical training at University College Hospital, London, to enter the Royal Field Artillery for service in the first world war, being awarded the French Croix de Guerre in 1918. Returning to University College Hospital in 1919, he qualified M.R.C.S., L.R.C.P. two years later. Entering the R.A.M.C. as a lieutenant immediately after qualifying, he transferred to the Royal Air Force Medical Service in 1922, with the rank of flying officer. For the next seventeen years he served mostly abroad, in Iraq and India, and when the second world war broke out in 1939 he was in charge of a mobile field hospital attached to the Advanced Air Striking Force, with the rank of wing commander. On returning to England he was placed in command of No. 1 Medical Receiving Establishment, and then, in March, 1941, he was appointed commanding officer of Princess Mary's Hospital, Halton. In 1944 he was principal medical officer to the 3rd Tactical Air Force in Burma, becoming deputy principal medical officer at the headquarters of Transport Command, South-east Asia, a year later. On his return to England in 1946 he became principal medical officer at the headquarters of Transport Command, until his appointment as commandant of the R.A.F. Central Medical Establishment. In 1947 he was appointed Deputy Director-General of R.A.F. Medical Services. Three years later he took the D.T.M.&H. of the English Royal Colleges. From September, 1950, he served as principal medical officer, with the rank of air vice-marshal, at the headquarters of Home Command, which at that time took over administrative control of R.A.F. hospitals and medical units in the United Kingdom from Technical Training Command. He retired from the R.A.F. at his own request in 1953. Barnes was a member of the Central Medical War Committee in 1949–50, and in 1954 he was elected to the Council of the British Medical Association, becoming an *ex officio* member of the Armed Forces Committee, of which he became chairman last year. He was appointed C.B.E. and an Honorary Surgeon to the King in 1951, becoming an Honorary Surgeon to the Queen the following year. He married Miss Kathleen M. King in 1923 and had one son.

J. M. K. writes: The name of William Edward Barnes will always have a foremost place among those who built up the medical branch of the Royal Air Force. The record of his service shows this, and points to his devotion and high achievement. But it cannot bring out the qualities which bound him to his friends. He made friends wherever he went and lost none.

He was indeed the best friend anyone could have, considerate to all, courteous almost in the fashion of an earlier day, generous in thought and action, frank when frankness was necessary, completely unselfish; above all—and this was characteristic—he did not change. This stability was perhaps a part of his enviable attitude to life. He saw his duty clearly and did it. He was not in doubt between right and wrong, and never compromised, his principle sustained by his firmness of purpose and his self-reliance. He could be stirred to anger, and three things roused him—slipshod work, evasion of responsibility, and injustice. Faced with these he spoke his mind vividly and to the point. Folding of the hands held no appeal for him, and to his latest days he was active, vital, and interested.

In the earlier years of his service, as a most able clinician, Barnes was meticulous in the care of his patients, seeing to

every detail which might be helpful whatever the cost in effort, and not only detail of medical treatment but matters of welfare or of personal or family concern. Any who would come between him and what he thought best for his patients had to reckon with a strong opponent. Later in his service he brought the same clear outlook to the wide administrative problems which fell to his care. His interest in his chosen Service never failed, and after his retirement he was eager as always for its advancement, and jealous for its reputation.

He was a cheerful and stimulating companion, and in his circle liveliness was assured. Those who knew him in the surroundings of his home are grateful for the memory of the real accord and the deep happiness of a united and devoted family. This true man will not be forgotten.

E. W. BAIN, M.B., F.R.C.S.

Mr. E. W. Bain, honorary consulting surgeon to the ear, nose, and throat department of the General Infirmary at Leeds, died at his home at Arkendale, near Knaresborough, Yorkshire, on July 15. He was 81 years of age.

Edward Walter Bain was born on March 11, 1877. He received his medical training at the London Hospital, graduating M.B., B.S. from London University in 1902. Five years later he was admitted F.R.C.S. After graduation he held a number of house appointments at his teaching hospital, and then undertook postgraduate study in Vienna. On his return to London he became senior clinical assistant in the ear and throat department at the London Hospital, assistant surgeon to the Metropolitan Ear, Nose, and Throat Hospital, and surgeon to the ear and throat department of the Royal Waterloo Hospital for Children and Women. A career as a London specialist seemed in prospect for him, but he moved to Leeds in 1912, when he began what was to be a long connexion with the General Infirmary there. For well over thirty years he was surgeon (ultimately senior surgeon) to the ear, nose, and throat department; and the Ikley Coronation Hospital, the St. James' Hospital, Leeds, and the Castleford, Normanton and District Hospital also had the benefit of his services over a long period. In addition, he was for some time clinical lecturer in diseases of the ear, nose, and throat in Leeds University. During the first world war he served as a captain in the R.A.M.C. at the 2nd Northern General Hospital. When he retired in 1937 he was appointed consulting surgeon in his specialty to the hospitals he had served so well. His retirement, however, was short-lived, for, soon after the outbreak of the second world war in 1939, he was recalled to active work, finally retiring in 1947.

O. C. L. writes: Edward Walter Bain came to Leeds from the London Hospital in 1912 on his appointment as surgeon to the ear, nose, and throat department of the General Infirmary at Leeds. It was to be a happy association lasting in an active way for almost thirty-five years, for he retired in 1937 but returned at the outbreak of war and remained in practice until 1947. He had a large, successful practice which extended throughout Yorkshire and the north, and his services were in big demand when the surgery of the acute mastoid was an important part of otology. He was a careful and deliberate surgeon with a leaning towards conservatism. He had a most equable and calm temperament and nothing ever seemed to disturb or excite him. He was extremely kind and courteous to all patients.

The generous hospitality of "Bill" Bain and his wife will be remembered by many older colleagues and friends who had the opportunity and pleasure of being entertained in the delightful houses they occupied; houses which were graced by beautiful old furniture, of which Bill Bain was no mean connoisseur. For many years he played golf at Alwoodley, and many of us, as students, first met Bill Bain when he organized the annual staff v. students match—and what a delightful encounter it was. In later years he became an enthusiastic fisherman, but throughout his life

his garden gave him greatest joy, and he was tending his flowers only a few hours before he died. During the last few years a neuralgia caused him a good deal of distress, but he was always happy to welcome old colleagues and friends to his home in Arkendale, and with great delight would show them round the garden and entertain them to tea. The death of his wife in 1943 was a severe blow to him, but he was fortunate to be cared for to the end by those who had served him loyally for almost forty years.

P. P. DEBONO, O.B.E., M.D., F.R.C.S., D.P.H.

Professor P. P. Debono died on June 3 in Malta, where for many years he was senior surgeon at the Central Hospital and professor of surgery in the university. He was 67 years of age.

Peter Paul Debono was born on June 29, 1890, and graduated M.D. from the University of Malta in 1910. As first student in his course he won a scholarship which took him to London for postgraduate study, and in 1911 he obtained the Cambridge D.P.H. Returning to Malta, he was assistant to the professor of anatomy and of pathology in the university until 1917. During the first world war he was acting pathologist at the Central Hospital, Malta, and civil surgeon attached to the Royal Navy and, later to the R.A.M.C.; assistant to the pathologist, Malta Command; and officer in charge of a district laboratory. After a period as medical officer of health in Malta in 1918-19, he returned to England for postgraduate surgical studies at St. Bartholomew's Hospital, and was admitted F.R.C.S. in 1920. In the following year he held the appointment of resident surgical officer at Manchester Royal Infirmary. From 1921 to 1926 he was junior surgeon at the Central Hospital, Malta, and he then became senior surgeon and professor of surgery in the university, retiring in 1951. From 1936 to 1939 he served on the Executive Council of Malta, and shortly after the beginning of the second world war he became chief surgeon of the emergency medical services. He was appointed O.B.E. in 1944. Elected to the Maltese Legislative Assembly in 1947, he became Minister of Health and, subsequently, Speaker of the Assembly. He was a member of the British Medical Association for forty-five years, being assistant secretary of the Malta Branch from 1919 to 1923, honorary secretary and treasurer from 1923 to 1930, and president from 1935 to 1937, and again in 1942-3. He leaves a widow and two daughters.

V. G. GRIFFITHS writes: Professor P. P. Debono established modern surgery in Malta. He combined in the highest degree intellectual abilities and skilled craftsmanship, and, coming to surgery by way of physiology and pathology, he proved an ideal teacher whose precept and example founded a sound surgical school in the island. His versatility was remarkable, and he had more than made his mark in bacteriology and pathology before his superabundant energies were providentially turned towards surgery. Even in his most hectic surgical period, however, his interest in natural history never flagged, and his students habitually regarded him as their mentor in practically every subject of the medical curriculum.

During the first world war, when Malta was "the Nurse of the Mediterranean," he was inspired by contact with Sir Charles Ballance and men of similar calibre who were treating the wounded from Gallipoli. His training in England made of him a teacher of the British school, and he was very well known to the leaders of British surgery of his time. The second world war, in which Malta occupied a most honourable front-line position, brought him the burden and the glory of treating almost single-handed the thousands of serious civilian casualties of enemy bombing: it is safe to say that no surgeon in the Commonwealth had a task of equal magnitude in operating for months and months of continuous bombardment in makeshift hospitals with the slenderest resources. Yet throughout that period he also coped successfully with routine surgery and with his teaching.

P. P. Debono was a true general surgeon of such high quality that the results of his incursion into any part of the human body could bear comparison with those of most specialist surgeons. His approach to surgery was lion-hearted, and his courage was matched by superb judgment and marvellous dexterity. He reached the peak of his achievement when he was yet denied those ancillary advances of anaesthesia and chemotherapy that we now almost take for granted. Surgery was not made easy for him, but he did seem to make it easy for others. He was magnificent in times of stress, when his own broad shoulders seemed made for the burdens of all around him: very seldom was he known to lose patience with his assistants, and never to stoop to blaming them when things went awry. He has created in Malta an example and a tradition which his pupils and successors are honoured in attempting to preserve.

CORRIE HUDSON, C.B., C.I.E., D.S.O., F.R.C.S.Ed.

Major-General Corrie Hudson, who had a distinguished career in the Indian Medical Service, died on July 11. He was 84 years of age.

Corrie Hudson was born at Clifton, Bristol, on April 5, 1874. Educated at Manilla Hall, Clifton, where his father, C. T. Hudson, F.R.S., was headmaster for some twenty years, he received his medical training at Charing Cross Hospital, qualifying M.R.C.S., L.R.C.P. in 1897. He then held the appointments of house-surgeon and house-physician at Charing Cross before entering the Indian Medical Service in 1899. From that year until 1907 he was medical officer with the 2nd Queen's Own Rajput Light Infantry, and with that regiment served with the China Expeditionary Force in 1900-2, becoming captain in the latter year. He was with the Somaliland Field Force in 1903-4 and was present at the action at Jidballi. His services there were recognized by a mention in dispatches and the award of the D.S.O. in 1904, as well as the medal and clasp. From 1908 to 1912 he was staff surgeon at Bangalore, promotion to major coming in 1910, and in 1912-13 he served in the war in the Balkans. He was elected F.R.C.S.Ed. in 1912. In November, 1914, soon after the outbreak of the first world war, he was appointed deputy assistant director of medical services with the 1st Indian Cavalry Division in France, and held the post until June, 1916, being mentioned in dispatches for his services. From 1918, when he was promoted lieutenant-colonel, to 1919 he was an instructor at staff schools in India, and from 1919 to 1923 an assistant director of medical services—first, with the Lines of Communication of the Waziristan Field Force in 1919-20, being mentioned in dispatches, awarded the medal, with clasp, and appointed C.I.E. in 1920; then with the Wana Column in 1921-1, again being mentioned in dispatches and receiving the clasp; and with the Razmak Field Force in 1922-3, with a further mention and clasp. In 1924-5 he was director of medical organization for war at Army Headquarters. He became colonel in 1925, and in 1927 was appointed C.B. From 1928 to 1932, when he retired, he was deputy director of medical services in the Eastern Command, with the rank of major-general, and an Honorary Surgeon to the King. His elder brother, Lieutenant-Colonel Charles Tilson Hudson, who died in 1948, also had a distinguished career in the Indian Medical Service. In 1904 Corrie Hudson married Miss Frances E. Barratt, by whom he had one daughter. Mrs. Hudson died in 1945.

KEITH CHITTY, M.B., F.R.C.S.

Mr. Keith Chitty, consultant surgeon to the mid-Worcestershire group of hospitals, died at his home at Chaddesley Corbett, near Kidderminster, on July 9. He was 38 years of age.

Keith Chitty was born on May 12, 1920, the son of Mr. Hubert Chitty, F.R.C.S., of Bristol. From Clifton he won an exhibition to Peterhouse, Cambridge, in 1938, and from

there he went on to University College Hospital to receive his clinical training, distinguishing himself by winning the Erichson prize in practical surgery. He qualified by taking the London Conjoint Diploma in 1943, and in the following year he graduated M.B., B.Chir. After holding the appointment of house-surgeon at University College Hospital, he served in the R.A.M.C. from 1944 to 1947. On return to civilian life he was appointed surgical registrar at his own teaching hospital, and in 1949 he obtained the F.R.C.S. From 1952 to 1957 he was a senior registrar at Bristol Royal Infirmary, for the first three years in the urological department, and then in general surgery. Last December he was appointed consultant surgeon to the mid-Worcestershire group of hospitals. He leaves a widow.

A. M. writes: The sudden death of Keith Chitty at the age of 38 when he seemed to be at the beginning of a satisfying surgical life has saddened his many friends. He had been appointed consultant surgeon to the mid-Worcestershire group of hospitals as lately as December 1, 1957, and had barely had time to begin his work there. Although he went almost straight away into the Army after qualification, and was among other things medical officer to the Royal Engineers who built "Mulberry Port," his interests were always in surgery and led him to be a surgical trainee when serving later in India until he left the R.A.M.C. in 1947. An interest in genito-urinary surgery and the prospect of returning to the West Country brought him as senior registrar to the urological department in Bristol in 1952. Here the greater responsibility and the wider practical experience produced an immediate response, and Keith Chitty developed into a clinician whose soundness and judgment were respected by all; he was an excellent example of the happy result of combining a sound basic knowledge of surgery with a kindly, reassuring manner and a real ability to inspire confidence in his patients. After three successful years in urology he changed over to general surgery and spent his last two years, before obtaining a consultant post, as senior registrar at the Bristol Royal Infirmary. His as senior registrar at the Bristol hospitals were legion: he was greatly liked by his colleagues, and his relationship with his chiefs was on the terms of a personal friendship. He was beloved by the nursing staffs and especially by the students, whom he taught thoroughly and with humour the basic bedside clinical surgery of which he was a master. It is true to say that he left Bristol with universal good wishes, and the news of his death was received with dismay and with the feeling that the world of surgery has been suddenly and unaccountably deprived of a member whose value and potential influence for good were very great indeed. His mother and father and his wife have our sincere sympathy in their tragic bereavement.

Dr. A. G. FREEMAN writes: The news of the death of Keith Chitty at the early age of 38 has been received with great sorrow by his many friends in Bristol. His loss has been keenly felt, especially by the junior hospital staff. As chairman for some time of the south-western regional junior hospital staff group and member of the executive committee of the group council he had done much to encourage and promote the welfare of his junior colleagues. Although he died on the threshold of his career as a consultant surgeon, the many appreciations received from his surgical colleagues of his work and skill speak for themselves. However, it is not in a professional capacity that I wish to add my personal tribute but rather as one who has had the immense privilege of friendship since we were undergraduates together at Cambridge some twenty years ago. Even in those days Keith knew that, like his father, he would become a surgeon. Soon after qualification his training was interrupted by war service, and as an Army doctor he landed in Normandy on "D" day. On demobilization he resumed his surgical training, and a few months before his death had achieved his ambition. To the casual acquaintance Keith may have appeared somewhat quiet and retiring in manner. Yet to those who knew him well it soon became evident that here was a man with a fine sense of

humour and with high ideals and a firmness of character which were to be admired. His quiet and friendly nature bred trust and respect. Before he left Bristol at the end of last year the housemen and registrars in the area gave a dinner in honour of Keith and two of his colleagues who had recently obtained consultant appointments. We felt at that time that we were wishing godspeed to our friends. Now we in Bristol mourn the loss of one who will be sadly missed, and our sincere sympathy goes out to his wife and to his family in their bereavement.

W. H. C. SPOONER, M.B., B.S.

Dr. W. H. C. Spooner's untimely death on August 1 through the ramming of his yacht by a tug at Brest has caused consternation and sorrow in the town and district of Blandford Forum, Dorset. He was 49 years of age.

William Henry Casswell Spooner was born on July 2, 1909, at Blandford, where his father, grandfather, and great-grandfather were all in general practice before him. Educated at Epsom College and at St. Mary's Hospital, he took the London Conjoint diploma in 1932 and the London degrees of M.B., B.S. two years later. After a period of residence in hospital and acting as assistant in Llandudno, he returned to his birthplace in 1936, where he went into partnership with Dr. K. J. T. Wilson and Dr. D. Oliver, following the retirement of Dr. L. Bodley Scott, and since 1954 also with Dr. D. I. T. Wilson. His knowledge of the locality, his sympathy, kindness, tact, and skill, enabled him to build up a large practice in a short time, and he held the esteem and affection of all who knew him. During the second world war he left his practice to serve as a medical officer in the Royal Air Force, attaining the rank of squadron leader. Apart from his work, his chief interests lay in yachting and in art. He was instrumental in founding the Blandford Forum Club and in organizing local art exhibitions. A physician, counsellor, and friend to his patients, a grand colleague, who always gave of his best, he continuously radiated to his friends, colleagues, and patients the finest qualities of his profession. He was a faithful and devoted servant to the people of Blandford and district, and both they and his partners have suffered an irreparable loss. The greatest burden of grief and sense of loss falls on his widow and three children, and to them the town and countryside and his fellow practitioners extend the most sincere sympathy.—K. J. T. W.

**A. K. COSGRAVE, M.C., M.B., B.Ch., L.M.
D.P.H., D.T.M.&H.**

Dr. A. K. Cosgrave, who was for many years a member of the Colonial Medical Service, died suddenly at Beaconsfield on June 20.

Alexander Kirkpatrick Cosgrave was born in 1885, and was a medical student at Trinity College, Dublin, graduating M.B., B.Ch. in 1909. Soon after graduation he went out to the Straits Settlements as a surgeon in the medical department there. When the first world war broke out in 1914 he was on leave in England and immediately joined the R.A.M.C., serving until the end of the war and attaining the rank of major. In 1918 he was awarded the Military Cross for his services. In the same year he obtained the Dublin D.P.H., and in 1920 the L.M. at the Rotunda Hospital and the D.T.M.&H. of the English Royal Colleges. In 1921 he transferred to the health branch of the medical department in the Federated Malay States to become health officer to the state of Negri Sembilan, where he did very good work, especially in connexion with the sanitation of the very malarious town of Gemas. Later, he was transferred to Kuala Lumpur as health officer, subsequently becoming senior health officer. In 1929 came a change in the medical organization. The federal post of chief health officer was abolished and the posts of senior health officer and senior medical officer, which existed in each of the four states of

the federation, were amalgamated to form for each state one combined medical and health administration. Dr. Cosgrave received one of these appointments, which he held until he retired in 1934. A few years before this he was chairman of the Federated Malay States Division of the B.M.A. After his return to Britain he settled at Beaconsfield, but throughout the second world war he again served in the R.A.M.C. A Fellow of the Royal Society of Tropical Medicine and Hygiene, he seldom missed a meeting after his retirement. Throughout his life he got on well with all classes of people, and his many friends will wish to extend their sympathy to his wife and family.

D. R. MURLEY, M.R.C.S., L.R.C.P.
D.Obst.R.C.O.G.

Dr. D. R. Murley, who was in general practice at Mullion, Cornwall, for most of his all-too-short professional life, died on July 6. He was 35 years of age.

David Ronald Murley was born on September 27, 1922, and brought up in Cornwall, where his father, the Rev. D. R. Murley, was vicar of Ludgvan. He was educated at Wellington School, Somerset, and at St. Mary's Hospital, where, after qualifying M.R.C.S., L.R.C.P. in 1945, he was obstetric officer. Joining the R.A.M.C., he served abroad in Saudi Arabia, attaining the rank of major. On returning to this country he was orthopaedic house-surgeon at the St. Mary's orthopaedic unit, at Park Prewett Hospital, and then returned to his beloved Cornwall, where he was in practice at Mullion. In 1949 he obtained the Diploma in Obstetrics of the Royal College of Obstetricians and Gynaecologists.

P. R. G. G. writes: It was with great regret that I learned of the death of Dr. D. R. Murley. As a medical student I shared a flat with him in London until he qualified, and knew him extremely well. Despite his rather serious looks he had a keen sense of humour, and he brought an unswerving loyalty and vigour to every task he undertook. Dr. Murley was also a keen horseman and tennis player, and he had that great gift of getting on equally well with young and old, rich and poor, wherever he happened to be. His death will be a great loss to those who knew him, and sincere sympathy is extended to his widow and two daughters.

C. H. writes: The sudden loss of David Murley is a personal tragedy to all who knew him well. An excellent doctor and a delightful companion, he combined integrity and deep sincerity with a cheerful outlook and ebullient sense of humour. Men of his character and temperament are rare: we shall not replace him in our life.

T. BEN THOMAS, M.R.C.S., L.R.C.P.

Dr. T. Ben Thomas, medical superintendent of Mount Pleasant Hospital, Swansea, and anaesthetist to the Glangawe Hospital Management Committee, died on July 12 after an operation. He was 60 years of age.

Thomas Ben Thomas was born at Swansea on October 23, 1897, and was educated at the Swansea Grammar School, Taunton School, and St. Bartholomew's Hospital. He interrupted his training to serve in the Army in the first world war. After qualifying in 1923 and doing some post-graduate hospital work, he settled in practice in Swansea, where he soon became a well-known and well-liked medical figure in the district. He built up a successful practice, but, much to his patients' regret, gave this up after some years to become medical superintendent of the Tawe Lodge Infirmary. During his lifetime he saw one of his greatest ambitions realized—the gradual transition of a good and well-run Poor Law institution, Tawe Lodge, to a modern and well-equipped and well-staffed hospital, the Mount Pleasant Hospital. He was the ideal person to be in charge during this transition period; it was in no small measure due to his drive, enthusiasm, tact, and perseverance that this change took place so smoothly and so steadily. His home and his hospital were always sources of great joy

and great pride to him. Although a busy man, he found time to be one of the honorary secretaries of the Swansea Division of the B.M.A. from 1937 to 1943, and eventually he became a very successful and popular chairman in 1951–2. Later, he acted, also very successfully, as joint charity steward of the Swansea Division, a post he held until his death. He was an active member of his Church and was also a freemason. He became president of the Rahere Society and captain of the Pennard Golf Club.

T. O. L. writes: Ben, as Dr. Thomas was known to us (Dr. Ben to his patients), was a lovable character. His cheerfulness, youthful exuberance, and sense of fun infected both his patients and his colleagues. He lived his life to the full, in work and play. Outstanding among his qualities were his kindness and his desire to help the sick and distressed without thought of himself. We in this community know how difficult it will be to fill the gap left by his death. He will be greatly missed and mourned for many a day by all who knew him, and we, in turn, extend our deepest sympathy to his widow and two daughters. It is a great privilege to have known him.

MARY T. PENRICE, M.B., Ch.B.

Dr. Mary Penrice, who was in general practice at Bebington, Cheshire, for nearly 30 years, died at Clatterbridge General Hospital on July 13 after a short and painful illness. She was 55 years of age.

The only daughter of a Birkenhead sea-captain, Mary Thompson Penrice was educated at Birkenhead and studied medicine at Liverpool University, where she graduated M.B., Ch.B. in 1926. After resident appointments and a short period in practice at Birkenhead, she settled at Bebington in 1930 and worked there whole-heartedly until her last illness. She was well known in the district, not only as a very careful doctor but also as a woman whose advice and help were always freely given to those who sought them. She upheld the highest professional standards, and her death is a blow to her patients and colleagues alike.—G. B.

Medico-Legal

FEMININE BEHAVIOUR

[FROM OUR LEGAL CORRESPONDENT]

Earlier this year (*Journal*, May 17, p. 1187) we reported a case in which the judge held that the behaviour of a husband in dressing up as a woman with the knowledge that it must cause his wife distress, a course of conduct which would ultimately have a serious effect on her health, amounted to cruelty. The wife was granted a decree of divorce. On May 22 Mr. Justice Davies (*The Times*, May 23) had to deal with the petition of another wife. She was married in April, 1950. In May, 1951, a child was born of the marriage, but apparently the husband had started shortly after the marriage to develop female characteristics, at any rate mentally. After consulting psychiatrists in 1952 and 1954 he was sent to hospital for treatment, and was given hormones with the express intention on the part of the doctors to accelerate and facilitate the development in him of female characteristics. The endocrinologist who with psychiatrists had advised this treatment said it was plain that the husband was suffering from a mental illness which made him to some extent feel like a woman and want to be a woman.

In 1957 the husband left his wife because of his desire to become a woman and because he could not stand living with her, and now dressed as a woman and was employed as a woman clerk. This naturally caused his wife revulsion.

Mr. Justice Davies held that the husband's consent to undergo hormone treatment for this mental illness was not cruelty on his part, since he could not help his illness any more than any other illness. He added that if the wife waited until May, 1960, she might get a divorce on the ground of desertion.

Medical Notes in Parliament

COMMONS REVIEW PROGRESS AND PROSPECTS OF HEALTH SERVICE

It was not to be expected that the Commons would allow the tenth anniversary of the National Health Service to pass without making it the occasion for a debate (the House of Lords having already had theirs); nor that on such an occasion Mr. ANEURIN BEVAN, its progenitor as Minister of Health in the 1945–50 Labour Government, would resist the opportunity to emerge from his preoccupations as "Shadow Foreign Secretary" in the Labour hierarchy for a foray into domestic affairs.

The speech with which he opened the debate on July 30 was a racy mixture of pride and politics. He went a long way back, to the period of preparation before the National Health Service Bill was brought, to pay a handsome tribute to the officials at the Ministry of Health, mentioning in particular Sir William Douglas, then the Permanent Secretary, and Sir Wilson Jameson, Chief Medical Officer, but embracing all in an expression of gratitude and appreciation for loyal, efficient, and inexhaustible service. The claim that the facilities the Health Service had provided to the population as a whole could be regarded as a marked success, and that there was general satisfaction with its therapeutic side, Mr. Bevan coupled with some party thrusts. So successful had it been that there was now competition in claiming paternity. He had even found Conservative members who had forgotten that they had voted against it on every occasion and for every conceivable reason. It had been said that all parties were in favour of it, but when he went to the Ministry of Health he found no evidence of that. Opposition was being whipped up—but he had been singularly fortunate in his opponents.

Free for All

Two conceptions underlay the Health Service. The first was to provide a comprehensive free health service for all at time of need. The second, which had been somewhat overlooked, was the redistribution of national income by a special method of financing the Service. On the first principle, there had always been more medical care in existence than the masses had been able to reach. It was that that the National Health Service was intended to put right. To-day, 98% of the population were registered with general practitioners. Not all the credit for the improvement in the nation's health went to the Service; there had been better standards of nutrition, and of housing, and new drugs. But the main point remained: all these drugs and medical facilities would not have been available under the old system. The new knowledge would be there, but it would not reach the people needing it. That was why the medical profession got it all wrong when it started to oppose the Service in 1946. Medical men seemed to believe, or some of them at least pretended to believe, that all nationalized medicine would do would be to interfere in the practice of medicine. He had had no such intention. What the Health Service was intended to do was to organize the practice of medicine in such a fashion as to reach the people who needed it most. That had been done.

Tax on the Better Off

On the financial side, he was getting a little worried. The insurance principle had been rejected at the inception of the Service as wholly inapplicable, and it was decided that the best and fairest way to finance the scheme was through the Exchequer, by general taxation, and those who had most would pay most. Conservative Members had been engaged in trying to reverse the redistributive aspect of the Service, and one of their chief supporters was the man who tried to stop it coming into existence at all, Dr. Charles Hill, Chancellor of the Duchy of Lancaster. The Treasury

through Mr. Dalton, took as an appropriation-in-aid that part of the contribution of the old National Health Insurance which had been used for medical benefits, amounting to about £41 millions. It had nothing to do with the Health Service, and was not paid to the Health Service. There was no organic, financial, or administrative link between the two. Although expenditure on the Health Service went up by £200 millions, the appropriation-in-aid remained the same.

The link between insurance and national health had been created in the minds of the Government to justify a tax on the poor. The contribution had been raised to £57 millions in 1957–8 and to £95 millions this year. By assuming the link the Government had called for more money from the National Insurance Fund instead of increasing taxation to provide the additional money. It was a transfer of the burden from the rich to the poor. He resented it because it was inimical to the second principle of the scheme, and because if persisted in it would appear to justify a gradual transfer of the whole cost of the Health Service to the shoulders of the poorest members of the community.

Pay-beds

After a reference to the great mischief done to the Health Service by continual changes in the Ministers at its head, Mr. Bevan turned to the pay-bed provision—a concession which was, in some cases, seriously abused. He received letters about it every week. The consultants, if they could get a paying patient into hospital, jumped the waiting-list and got him in. There was no justification for saying that in every instance it was for medical reasons. It was for financial reasons. He did not for a moment say this was universal, that it was so grave as to impair the Service, but it had caused great grief. He hoped this kind of thing would stop. If it was, the whole climate of the Service would be much happier, and the hospitals much more wholesome. If it was not stopped, then, in spite of the fact that some consultants might take him to court, he would send their names to the Minister—and not even try to claim qualified privilege.

Minister's Reply

Mr. D. WALKER-SMITH, Minister of Health, began his reply with some ripostes to Mr. Bevan's "highly selective remembrances" of things past, acknowledging in the process that no one would wish to grudge him any of the credit due for the inception of the Health Service, but was more concerned with the pattern of the future. One of the things that had turned out better than some had expected in the 10 years had been that the strength of the voluntary work in the Health Service and hospital work had continued unabated. There was still a sound basis of voluntary work, freely given and highly regarded.

The country was getting a good bargain for the very large amount the Health Service was costing. There was an increase in the number of effective beds in hospitals, greater speed and efficiency of treatment, and a great increase in the range of drugs to heal and vaccines to prevent disease. But there was not a universal pattern of success to match the conquest of diphtheria and the approaching conquest of tuberculosis. On the other side was the upward curve in cancer of the lung, leukaemia, and arteriosclerotic diseases. In this, as so often in this imperfect world, the successes left their problems. By increasing the expectation of life they put greater emphasis on the malignant and degenerative diseases of the later years.

Value of Prevention

Two signposts to future action were provided by the success with tuberculosis and diphtheria. One was the importance and potential of preventive medicine and action; and second, the contribution that could be made towards a solution of the accommodation problem in hospitals by the virtual elimination of some diseases. He was anxious to apply the principle of preventive medicine wherever possible. A heavy programme of vaccination

against poliomyelitis had been carried through this summer. One had to tread very delicately on this unpredictable ground, but it was perhaps significant that up to and including the 29th week of this year there were fewer cases, and fewer paralytic cases, than in the same period in any previous year, and the figures were far below the average. Another promising preventive measure was the fluoridation of water supplies against the incidence of dental decay. He hoped that in the areas concerned the people would appreciate its benefits and understand that there was no harmful effect from it. Mr. J. BAIRD (Wolverhampton, North-East, Lab.) here interrupted that the results of the experimental schemes could not be studied until 1962. Why not take action now, on the ample evidence from towns in England and from the U.S.? Mr. WALKER-SMITH told him they would rather see a continuance of the policy of demonstration on which they were embarked.

Planning for an Ageing Population

The impact of age structure on the changing pattern of disease was one of two great special problems which must condition thinking and planning for the future of the Health Service. By 1975 one person in seven would be over 65 years old, compared with one in 21 at the beginning of the century. Extended expectation of life must be accepted as a challenge to be met. There was a double duty: socially, to see that the increased span of life was a time of happiness; and economically, to see that looking after the old did not place an undue burden on the working community. The policy, therefore, was to seek to keep the elderly in their homes as long as possible, and when they had to go to hospital to rehabilitate them wherever possible. Two encouraging developments were that there had been a steady rise in attendances at chronic sick and geriatric clinics (from 7,000 in 1950 to 39,000 last year); and on the in-patient side, although there had been only a small increase in the number of beds a better use of them had enabled more patients to be treated. There were now over 70 geriatric departments, and more would be set up as resources permitted.

The other great special problem was mental health. More than two out of five hospital beds were devoted to those suffering from mental disorder. The Royal Commission had recommended, among other things, the abandonment of the assumption of the need for compulsion in favour of the offer of care without deprivation of liberty. The review of existing patients he had asked for in January to give effect to this as far as possible without legislation was in progress. Approximately 18,000 recommendations for discharge from compulsory powers had been received by the Board of Control, and about 12,000 accepted. Only about 100 had been refused. Examination of the remainder was continuing. Over the whole field of practice and procedure in mental health, Parliament would have the opportunity when the time came for mental health legislation to add to the volume of social progress a notable new chapter on this very human theme.

Efficiency in Hospitals

Whatever success was achieved in the policy of out-patient treatment, there would always be an important residue calling for in-patient treatment. The hospital service would always loom large; running costs took 54% of expenditure on the Health Service. Obviously it was necessary to seek the highest common factor of efficiency and economy. Organization and method studies were a constructive challenge to tradition, and should be accepted as such. The results could be dramatic, particularly in manual work. These potential savings were a hidden reserve of the greatest value. The development of this work should be encouraged, and its good results demonstrated to hospital authorities as fully as possible. The present experimental unit in the Ministry was to be enlarged and made permanent. A group of management consultants had offered to undertake a series of surveys at their own expense to

demonstrate the economies and improvements in efficiency which could be achieved in the hospital service. He had accepted the offer, and had suggested four subjects for investigation. The Royal College of Nursing had suggested that an advisory council on work study should be set up, and he would consult the other interests involved before settling the role and membership of the council.

Points from the Debate

Dr. A. D. D. BROUGHTON (Batley and Morley, Lab.), speaking about mental illness and overcrowded hospitals, said he hoped the Minister would resist pressure to build new hospitals to relieve the congestion. Mental cases should be sent into residential hospitals only if that was absolutely unavoidable. He advocated the extension of day hospitals, out-patient departments, psychiatric clinics, and domiciliary services.

Mr. JOHN CRONIN (Loughborough, Lab.), on the theme that neither doctor nor consultant had any incentive to consider economic questions, said that general practitioners were competing to obtain patients, and had a more or less blank cheque on the finances of the Service. Similarly consultants, in prescribing and ordering ordinary treatment, were completely autonomous. There was no doubt it would be possible for hospital consultants to treat patients more economically. The medical profession had co-operated with the Health Service in a remarkable way, but few had any idea of the economics of the Service. There was a case for some sort of administrative control of the medical profession itself.

Dr. EDITH SUMMERSKILL (Warrington, Lab.) deplored the general practitioner's lack of adequate training in psychiatry. Prescriptions were often written solely to terminate a protracted but necessary interview in a busy surgery with a patient suffering from some form of neurosis. Did the system that had been evolved encourage a doctor to be frank, and to refrain, whenever possible, from sending people to hospital? The surgical waiting-lists were so long, and falling so slowly, that more facilities were needed. She invited the Minister to consider territorial redistribution for long waiting-lists.

Parliamentary Secretary Winds Up

Mr. RICHARD THOMPSON, the Parliamentary Secretary, in his reply to the debate, expressed general agreement with the points made by Dr. Broughton, and assured him that the kind of objectives he had in mind were desirable ones that the Ministry intended to pursue.

The general practitioner was the key man in the non-hospital medical services. Through the executive councils and in other ways they wanted to build up his position in the Health Service and to ensure that it was one of proper status and importance. It was not true, as had been suggested, that because of insufficient co-operation among the various arms of the Service the general practitioners were working in isolation. The increase in partnerships, which helped to produce effective co-operation, had been notable. There were now about 68% of practitioners in partnership, compared with 50% in 1948. Group practices had also been encouraged with the aid of loans.

Of the drug bill, estimated to cost £74 millions, he pointed out that 40% would go to chemists for overheads and the services they provided, and 60% for the wholesale cost of drugs and dressings. An inquiry in 1955 revealed no evidence of excessive prices, but the Ministry were quite prepared to renew the inquiry if they judged it necessary. The scheme for voluntary regulation of prices covered 90% of proprietary preparations. When first applied in 1957 it resulted in 285 price reductions and an estimated saving of £400,000 a year. A much more substantial final report from the Hinchliffe Committee was on the way, and the closest attention would be paid to the recommendations. Some immediate administrative steps were being taken on the interim recommendations, and the appropriate organizations consulted on further action.

MEDICAL ACT, 1956

The Medical Act, 1956 (Amendment), Bill was read the third time and passed in the House of Lords on July 24, and on August 1 received the Royal Assent.

PNEUMOCONIOSIS AND BYSSINOSIS APPEALS

The Draft Pneumoconiosis and Byssinosis Benefit Amendment Scheme, 1958, was approved by the Commons on July 24. Mr. W. VANE, Parliamentary Secretary, Ministry of Pensions and National Insurance, explained that the Pneumoconiosis and Byssinosis Benefit Act was designed to bridge the gap between the old Workmen's Compensation Acts and the new Industrial Injuries Act. The adjudication provisions followed the pattern of the compensation Acts, and the decision on the cause of death was made by the Silicosis Medical Board, from which there was no appeal. The draft scheme was in no sense a criticism of the board, but experience had shown that this could be improved and some appeal allowed. The decisions were not wholly medical; there were also legal implications. The draft scheme substituted the adjudication procedure familiar under the Industrial Injuries Acts. The cause of death would be determined by the insurance officer, with medical advice, and from his decision a right of appeal would lie to the local appeal tribunal, and there could be a further appeal to the Commissioner. No large number of appeals was expected, but experience suggested that a few people would have been better satisfied if they had been able to exercise a right of appeal.

QUESTIONS IN THE COMMONS

Charing Cross Hospital

Mr. G. RIPPON (Norwich, South, C.) asked the Minister of Health on July 29 whether he had reached a decision regarding the future of Charing Cross Hospital.

Mr. WALKER-SMITH stated that on February 9, 1955, the House was informed by the then Minister that the Government's plans for hospital building expected to start in the next few years included a project for the rebuilding of Charing Cross Hospital at Northwick Park, Harrow. This proposal had had to be abandoned because further consideration by the University of London and the University Grants Committee caused these bodies to decide that it was not in the best interests of medical education to remove the Charing Cross Hospital Medical School to Northwick Park.

The existing Charing Cross Hospital building is outmoded and inadequate for hospital purposes and it cannot be properly redeveloped on the same site. To meet university requirements the new site must be within reasonable access of all the facilities of the university, including the basic sciences and general student activities, and in August last the responsible hospital authorities were asked to consider the possibility of rebuilding on the site of the existing Fulham Hospital, which was in close proximity to these university facilities and which also required rebuilding.

I am glad to say (he continued) that a large measure of agreement has been reached by the responsible hospital authorities about the practicability of amalgamating Charing Cross Hospital, the West London Hospital, the Fulham Cross Hospital, and the Fulham Maternity Hospital as a first step towards the ultimate replacement of all of them by a new general teaching hospital at Fulham.

I have given close and careful consideration to all the representations made to me, including those made by the committee headed by the Mayor of Fulham, and I am satisfied that the Board of Governors of Charing Cross Hospital in close co-operation with the South-West Metropolitan Regional Hospital Board will provide a service to the locality which will compare favourably with that which might have been provided by the rebuilding of Fulham Hospital as a non-teaching hospital. I propose, therefore, to make arrangements for the proposed regrouping at the earliest practicable date so that the replanning of the new teaching hospital may proceed without delay. The necessary

facilities for clinical teaching will be provided at the new hospital, but the question of preclinical facilities is under consideration in consultation with the university and the University Grants Committee.

Scope of Inquiry into Artificial Insemination

Mr. R. A. BUTLER, Home Secretary, announced on August 1 that the terms of reference of the proposed committee on human artificial insemination were to be

To inquire into the existing practice of human artificial insemination and its legal consequences and to consider whether, taking account of the interests of individuals involved and of society as a whole, any change in the law is necessary or desirable.

The Earl of Feversham had agreed to serve as chairman. He hoped shortly to announce the names of the other members of the committee.

Russian Multiple Sclerosis Vaccine

Mrs. JOYCE BUTLER (Wood Green, Lab.) asked what further details the Minister had been able to obtain of the New Zealand experience of the Russian multiple sclerosis vaccine. Mr. WALKER-SMITH replied that he had received no further details from New Zealand. The replies received to inquiries which were addressed to the Soviet Union were being studied.

A letter published in the *British Medical Journal* for July 26, from Dr. A. K. Shubladze, of Moscow, and Professor G. W. A. Dick, of the Queen's University, Belfast, said that they thought it clearly necessary to reinvestigate and characterize the original isolates of the virus from which the vaccine was prepared, as recent experiments had shown that the strain in current use was similar to rabies virus. So far as treatment with the vaccine was concerned, they said that it was not possible to make any further recommendation until reinvestigations had been made. This latest information made it clear that both the efficacy and the safety of this vaccine were at present in doubt.

B.M.A. Conference and Merit Awards

Mrs. JEGGER (Holborn and St. Pancras, South, Lab.) asked the Minister what communication he had received from the British Medical Association's annual conference on the subject of merit awards; and what reply he was making thereto. Mr. WALKER-SMITH: None.

Institute of Criminology

Mr. BUTLER announced on July 31 that he had been informed by the Vice-Chancellor of Cambridge University that, provided the necessary funds could be made available, the university would be glad to consider the establishment of an institute of criminology, whose functions would include both teaching and research, as well as facilities for exchange of views and information with those concerned with the practical administration of the law. The nucleus of the institute would be the existing Department of Criminal Science, but it would be developed on a broader basis, and steps would be taken to associate all interested faculties with its management.

Universities and Colleges

UNIVERSITY OF DURHAM

At Congregations held on July 4 and 5 the following degrees and diplomas were conferred:

M.D.—G. S. Anderson, *G. Pringle, *G. A. Stirling.
M.B., B.S.—J. Anderson, W. V. Anderson, Margaret S. Atkins, Judith C. H. Bullen, Margaret S. Burrill, Mary Bynon, I. G. Campbell, J. Cape, Jean Carr, Ben-Zion Chalk, J. R. Cox, W. G. Donald, C. M. Dunn, L. E. Dunn, Elizabeth Elliott, M. A. Ferri, G. Gill, C. P. Gillie, H. L. Goldwater, R. Heslop, D. H. Irvine, Fiona M. Lehmann, Margaret A. Lewis, T. Lind, J. B. McCafferty, A. J. McComas, C. H. McCulloch, A. Malcolm, P. F. Moran, J. M. Morrison, H. N. Murray, H. Narvik, Sarah H. J. Nelson, S. A. Oduntan, I. L. T. Oluwole, A. Powney, D. G. Proudler, D. N. Raine, D. Rankin, M. F. Reece, E. Ross, Dorothy A. Stevenson, J. R. C. Stubbs,

Margaret A. Stubbs, E. Taylor, I. H. Taylor, S. Tetlow, Jean B. Thompson, P. R. Uddall, M. Ward, Joan M. Whitmore, P. G. Wood, P. H. Yorke, *P. M. Calamel.

DIPLOMA IN PUBLIC HEALTH.—Jean M. Bainbridge, Florence Cadogan, Marion Harrison, T. W. L. Knaggs, June K. Lloyd, R. T. Pagan, Doris Story.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—E. S. Lower.
*In absentia.

UNIVERSITY OF MANCHESTER

The following candidates have satisfied the examiners at the examinations indicated:

D.P.H.—Margaret Armistead, H. Bailey, Irene S. Bailey, A. D. Bostock, J. R. Brown, A. S. Dunn, B. R. Ellis, A. Gatherer, R. E. Jones, W. Lees, Joyce E. Leeson, J. E. Morris, D. W. Preston, Rachel D. R. Sasieni, H. R. Simpson, D. H. Vaughan.

UNIVERSITY OF BIRMINGHAM

Professor W. Melville Arnott will represent the University at the second World Conference on Medical Education to be held in Chicago from August 29 to September 4, 1959.

Mr. A. L. d'Abreu has been appointed to the board of governors of the United Birmingham Hospitals.

Professor J. W. Orr has been reappointed to the Birmingham Regional Cancer (Co-ordinating) Committee for the year ending March 31, 1959.

The title of University Research Fellow has been given to the following during the tenure of their present posts: *Department of Medicine*, Dr. L. A. G. Davidson, senior medical registrar, Queen Elizabeth Hospital; Dr. Mary Bateman, Endowment Fund Research Fellow, Queen Elizabeth Hospital; Dr. N. Segel, Nuffield Fellow, *Department of Experimental Pathology*, Dr. G. M. Aber, medical registrar, Queen Elizabeth Hospital.

Dr. F. N. Garratt has been appointed Research Fellow in Social Medicine from July 1, 1958.

The following have resigned their appointments from the dates indicated in parentheses: Dr. K. Aterman, Senior Lecturer in Biophysics in the Department of Anatomy (July 31, 1958); Mr. P. G. Bevan, Lecturer in Surgery (July 15, 1958); and Dr. K. R. Thornton, Lecturer in Pathology (September 30, 1958).

The University has accepted the offer of Dr. Arthur Beauchamp, a former student of the Medical School, to endow an annual prize to be awarded for the best essay on some aspect of general practice.

In Congregation on July 5 the following degrees were conferred:

Ch.M.—K. D. Roberts, R. W. Tudor.
Ph.D.—In the Faculty of Medicine: *L. Kornel, J. C. Lawrence, D. G. Moulton.

M.B., Ch.B.—1. A. J. G. Campbell, 2. A. J. Fawcett, 3. B. Goodhead, T. R. Abbott, Ada M. Adams, D. Atkinson, Ann I. Ballantine, A. D. Barnes, Ruth Barton, Vivien E. Basco, L. S. Bernstein, *C. Berry, J. E. Bewley, K. S. Bhogal, H. E. Black, A. W. Burdon, Brenda M. Chant, A. C. Cottrill, D. C. Crawford, J. T. Davies, P. W. Davis, D. G. Emery, Sylvia D. Gardner, Catherine M. Gay, *J. R. Geddes, *Jean M. Gibbon, S. Glick, M. G. S. Golby, I. G. Goldman, R. W. Griffin, R. G. Harrison, Frances E. Heron, M. J. Hoare, G. B. Hunt, S. E. O. Jones, M. Joorey, *Menigha Kemmer, *A. B. Lavelle, M. Lewis, Edna J. Lloyd, Wendy I. McNeilly, G. L. Morgan, Philippa N. Mourant, M. G. Mullin-Feroze, *K. Newbold, D. M. Nicoll, B. A. Oni-Okpaku, C. E. Oxenard, Doris H. Pereira, C. R. Phillips, P. R. Preston, Susan E. M. Richards, *C. J. Roberts, R. N. Smith, D. B. Southall, *Sheila M. Statham, Margaret S. Taylor, *C. W. Thompson, *F. R. Wallford, A. West, Nora E. Wild, T. H. Willits, P. J. Witherow, D. A. K. Woodward.

The following scholarships and prizes were awarded: *Queen's Scholarships*.—Final year, F. J. Fawcett; Fifth year, A. Rhodes. *Ingleby Scholarships*, J. R. Geddes (obstetrics and gynaecology), A. J. G. Campbell (paediatrics and child health). *Special Undergraduate Scholarships*, A. R. Beebejaun, G. B. Gelling, Margaret G. Hudspeth, E. A. Jones, H. G. Percival, Diana M. Price, K. Prowse, D. Sampson, M. Thomas, W. J. A. Westwood. *Arthur Foxwell Memorial Prize in Clinical Medicine and Beckwith Whitehouse Prize in Obstetrics and Gynaecology*, F. J. Fawcett. *Sampson Gamgee Memorial Prize in Surgery and Joseph Sankey Prize in Clinical Surgery*, C. W. Thompson. *"Queen's Hospital" Joseph Sampson Gamgee Prize in Surgery*, A. D. Barnes. *Cyril Raison Prize in Surgical Diseases in Children and Russell Memorial Prize in Nervous Diseases*, B. Goodhead. *Priestley Smith Prize in Ophthalmology*, B. Goodhead and C. J. Roberts. *Douglas Marsh, Ear, Nose, and Throat Prize*, G. R. Horton. *Leith Newman Medical Prize in Pathology*, R. M. Finch. *Bostock Hill Memorial Prize in Social Medicine*, A. Rhodes. *Bertram Windle Prize in Anatomy*, A. Wakeling. *John Barritt Melson Memorial Prize in Physiology*, H. G. Percival. *Peter Thompson Prize in Anatomy*, Dorothy J. Bicknell.

*With second-class honours. *Distinction in paediatrics and child health. *Distinction in obstetrics and gynaecology. *Distinction in surgery. *Distinction in medicine. *Distinction in pharmacology and therapeutics. *Distinction in social medicine. *Distinction in forensic medicine and toxicology. *In absentia.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—B. J. Fairhurst, A. W. Howel-Evans, E. A. Nieman, J. R. Roberts, D. Taylor-Robinson, D. J. West.

Ph.D.—In the Faculty of Medicine: K. Devakul.

Ch.M.—E. C. Edwards, J. H. Y. Fung.

M.B., Ch.B.—1. R. Harris, 2. May B. Jones, H. M. Alty, A. L. Ansdell, W. K. H. Barnard, J. M. Beresford, G. N. Bhadesra, J. N. Boardman, Mary J. Boardman, M. J. Brindle, A. Broughton, T. N. Calvey, R. P. Christian, P. Cochrane, R. L. Coupe, Marie T. Cox, D. G. Ellis, E. R. Evans, R. E. Fallowfield, R. S. Ford, W. Green, Malvina Harris, J. Higham, L. J. Hipkin, Anne T. Irvine, J. A. Jackson, Anne Jacques, A. W. Jones, D. Jones, E. W. Jones, K. E. Jones, R. H. T. Jones, J. F. Kane, W. E. Kearns, N. B. Kirkland, K. Lilley, W. F. W. E. Logan, H. Martin, Maureen D. Martin, K. Martindale, P. J. Moorhead, Evelyn J. Moss, D. L. Parry, H. J. Phillips, G. H. Prince, P. G. Rae, G. B. Riley, Catherine O. L. Rimington, Aline M. Robertson, R. F. Robertson, C. Roby-Jones, J. M. Romer, Yvonne A. Roope, C. E. Sissons, J. F. Taylor, J. M. Taylor, R. W. Taylor, V. R. Taylor, N. E. Thomas, D. E. Wallace, R. Whitehead, J. G. M. Williams, J. A. Wilson, J. S. Wright, *W. D. R. Writer, C. Wynne. Passed in separate subjects: D. Cooper, R. F. Evans, and J. F. Farrall (surgery and obstetrics and gynaecology); D. D. Hughes (medicine and obstetrics and gynaecology); D. A. Hutchinson, G. W. Jones, and I. E. Roberts (medicine and surgery).

DIPLOMA IN PUBLIC HEALTH.—Sheila I. Angles, Cynthia J. Bladon, P. J. Burke, D. C. Curtin, A. Depares, Cecilia T. Diskin, F. R. Howell, J. V. Loughlin, Anne D. Micah, S. Naylor, J. M. V. Packer, J. A. Seddon, D. Wild.

DIPLOMA IN RADIOLOGY.—Radiodiagnosis: Varunee Amatyakul, E. H. Burrows, L. R. Levin, T. Nopparat, R. G. Putman, H. G. Row. Radiotherapy: A. K. Bose, G. A. L. G. Blazebrook, R. Spencer.

*With second-class honours. *Distinction in surgery. *Distinction in obstetrics and gynaecology. *With distinction.

UNIVERSITY OF BRISTOL

Dr. T. J. Betteridge and Dr. L. A. Faigan have been appointed Demonstrators in Pathology.

Vital Statistics

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in June was 116, compared with 87 in the previous month and 91 in June, 1957.

The numbers of cases of industrial diseases in the United Kingdom reported during June, 1958, were as follows: lead poisoning 2, aniline poisoning 1, compressed-air illness 1, anthrax 1, epitheliomatous ulceration 19, chrome ulceration 24; total 48. There were no deaths. *Ministry of Labour Gazette*, July, 1958.

Week Ending July 26

The main feature of the return for England and Wales in the week ending July 26 was an increase in the notifications of food-poisoning by 154, from 332 to 486. Small fluctuations were recorded for other diseases. These included increases of 21 for scarlet fever, from 651 to 672, and of 6 for acute poliomyelitis, from 57 to 63. Falls in notifications were recorded for whooping-cough 78, from 827 to 749, measles 80, from 6,674 to 6,594, dysentery 75, from 712 to 637, and pneumonia 38, from 220 to 182.

The 63 notifications of poliomyelitis comprised 38 paralytic and 25 non-paralytic, which were respectively 1 more and 5 more than in the previous week. The largest return was from Yorkshire West Riding 16 (Leeds C.B. 5, Halifax C.B. 2, Normanton U.D. 2).

Two large outbreaks of food-poisoning were notified: Denbighshire, Abergele U.D. 139, and Lancashire, Formby U.D. 80.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the years 1949-57 are shown thus ———, the figures for 1958 thus ———. Except for the curves showing noti-

fications in 1958, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending July 19 (No. 29) and corresponding week 1957.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the whole of England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenzal pneumonia.
‡ Includes puerperal pyrexia.

Medical News

Royal College of Physicians.—At the Quarterly Comitia held on July 31 with Dr. ROBERT PLATT, President, in the chair, the following officers were elected:

Censors: Drs. J. R. H. Towers, E. R. Cullinan, E. R. Boland, and J. C. Hawksley. *Treasurer:* Dr. R. R. Bomford. *Registrar:* Sir Harold Boldero. *Harveian Librarian:* Sir Charles Dodds. *Assistant Registrar:* Dr. J. R. Ellis. *Library Committee:* Drs. C. E. Newman, W. S. C. Copeman, W. Brockbank, and W. H. McMenemey. *Finance Committee:* Drs. L. C. Martin, J. F. Stokes, and J. W. D. Bull.

M.R.C.P.—The following, having satisfied the censors' board, have been admitted members of the Royal College of Physicians of London:

C. H. Ashton, G. V. Balmforth, J. L. T. Birley, D. F. Cappell, J. R. Curtis, C. T. Dollery, E. B. D. Dowdle, D. W. Evans, K. F. Fairley, O. W. Hill, W. B. Jackson, J. V. Jones, N. F. Jones, H. R. Klein, R. E. Lovelace, M. W. McNicol, V. Parsons, D. J. Patel, J. S. Penington, R. W. B. Penman, E. V. Pieris, A. Pollard, D. H. H. Pullon, A. M. Rankin, M. D. Readett, J. L. Reed, S. M. Richards, C. E. Rotem, H. H. Shawdon, C. K. Simpson, J. G. Sloman, M. A. Smith, A. E. Stevens, Squadron-Leader D. J. Stoker, M. W. Swallow, A. K. Thould, G. E. G. Williams, I. V. Wilson, J. Wilson, S. M. Woodcock, K. J. Zilkha.

Royal Medical Benevolent Fund.—At the annual general meeting held on July 30 the following honorary officials were re-elected: president, Sir HENRY TIDY; honorary treasurer, Mr. F. A. JULER; and honorary secretary, Dr. T. ANWYL-DAVIES. During 1957 the Royal Medical Benevolent Fund disbursed a total of £43,942 in grants and annuities. 97 of the 398 cases helped by grants were new. The annual report points out that the total number of people who benefit is much larger than the "cases," since many of these include married couples, children requiring financial help and education, and widows with families. Emphasizing the need for new subscribers, the report goes on: "Surprisingly enough, many of the profession do not know of its [the Fund's] existence or of its work. Many gladly subscribe when their attention is drawn to its purpose of acting as a Good Samaritan to the whole of the medical profession."

Royal College of Surgeons.—At a meeting of the council of the College on July 31 Lieutenant-Colonel R. H. ROBINSON, R.A.M.C., was awarded the Mitchiner Medal, and Wing Commander W. B. THORBURN was awarded the Lady Cade Medal. The award of the Gilbert Blane medal to Surgeon Commander W. E. CROCKER, R.N., was reported. The Hancock prize was awarded to Mrs. E. M. COOKE, of the Royal Free School of Medicine.

Medical Insurance Agency.—The thirtieth annual meeting of the Medical Insurance Agency was held in B.M.A. House on July 24. New records of business were achieved in all branches of the Agency's work last year, and new high levels of profits were allocated to the medical charities. Two new members were elected to the Committee of Management, Sir RUSSELL BRAIN and Sir CECIL WAKELEY. Retiring members re-elected were Dr. J. FENTON, Sir ARCHIBALD GRAY, Mr. A. M. A. MOORE, Mr. R. W. RAVEN, Dr. O. L. S. SCOTT, Mr. BEN THOMAS, and Sir HENRY TIDY. Dr. FENTON was re-elected chairman and Dr. HENRY ROBINSON as honorary secretary; a vote of thanks was passed to both of them for their services during the past year. The report of the committee contained an emphatic tribute to the work of the general manager, Mr. A. N. DIXON, and his staff.

Protein Extraction.—Among recent Rockefeller Foundation grants is one to help Dr. N. W. PIRIE, F.R.S., and his colleagues to help develop their machine for extracting edible protein from waste vegetable matter. The work is being carried out at the Rothamsted Experimental Station, Harpenden, Herts.

Biosynthesis of Protein.—The Royal Society has awarded a Mr. and Mrs. John Jaffé donation studentship from

October 1 to Dr. Jennifer Wildy to work on the biosynthesis of the protein and haem components of haemoglobin in the department of chemical pathology, University College Hospital Medical School.

Dr. W. J. H. Butterfield has been appointed to the university chair of experimental medicine tenable at Guy's Hospital Medical School.

Surgeon Captain C. B. Nicholson has been appointed an honorary surgeon to the Queen in succession to Surgeon Rear-Admiral E. T. S. RUDD.

COMING EVENTS

British Association for the Advancement of Science.—Annual meeting, August 27 to September 3, in Glasgow. Details from the association, 18, Adam Street, Adelphi, London, W.C.2.

Institute of Biology.—Symposium on "The Effects of Pollution on Living Material," September 25 and 26, at the Royal Geographical Society, London, S.W.7. Further details from the general secretary of the Institute of Biology, 41, Queen's Gate, London, S.W.7.

Sixth International Congresses on Tropical Medicine and Malaria.—To be held in Lisbon from September 5 to 13. Further information from Professor Dr. MANUEL R. PINTO, Instituto de Medicina Tropical, Lisbon, Portugal.

International Association of Gerontology.—First meeting of the European Clinical Section, October 1-4 in Sunderland. Details from Dr. E. WOODFORD-WILLIAMS, Department of Geriatrics and Medicine, the General Hospital Chester Road, Sunderland, Co. Durham.

South African Paediatric Association.—Fourth congress, October 9-11, at the Pretoria Hospital. Further details from the secretary, Dr. E. FASSER, 201, Medical Centre, Pretoria, South Africa.

Conference on General Practice.—The *Medical World* is holding a conference on October 26 at the Victoria Halls, Bloomsbury Square, on general practice topics such as emergencies, rehabilitation, and the doctor-patient relationship. Admission by ticket (10s. 6d.). Further details from the *Medical World*, 55-56, Russell Square, London, W.C.1.

NEW ISSUES

Abstracts of World Medicine.—Issued in the first week of each month, this journal contains abstracts of important papers selected from the current medical literature of the world. Annual subscription £4 4s.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Friday, August 15

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. N. C. Oswald: clinical demonstration.

APPOINTMENTS

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—K. M. Mackenzie, M.D., M.R.C.P., Part-time Consultant Physician, West Suffolk General Hospital; J. H. Roberts, M.B., Ch.B., Radiological Registrar, Ipswich and East Suffolk Hospital; J. H. A. Black, M.B., B.Ch., and D. F. Craggs, M.B., B.S., Registrars in Psychiatry, Fulbourn and Addenbrooke's Hospitals; H. L. Clarke, M.B., B.S., Anaesthetic Registrar, Newmarket General Hospital.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Ostlere.—On July 29, 1958, at King's College Hospital, London, S.E.1, to Mary (formerly Patten), M.B., Ch.B., M.R.C.P.Ed., F.F.A.R.C.S., and Gordon Ostlere, M.B., B.Chir., F.F.A.R.C.S., of 22, St. George's Road, Bickley, Kent, a daughter—Katharine Mary.

Shemilt.—On July 25, 1958, at Salisbury Infirmary, Wilts, to Janet (formerly Brownscombe), wife of Mr. Philip Shemilt, a daughter.

DEATHS

Smith.—On July 24, 1958, at his home, Ascot, Berks, Malcolm Arthur Smith, M.R.C.S., L.R.C.P., aged 82.

Upton.—On July 22, 1958, in hospital, Bryan Harold Burgin Upton, M.B., Ch.B., of "Brentwood," Long Street, Dordon, Tamworth, Staffs.

Worthington.—On July 23, 1958, at the home of his son, Stanley Worthington, M.D., D.P.H., B.Hy., of the Grange, Leeds.

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Prednisolone and Pregnancy

Q.—Is pregnancy in a young woman being treated with prednisolone, 5 mg. daily, for severe eczema an indication for stopping treatment?

A.—This dose of prednisolone is very unlikely to have any effect on pregnancy or on the foetus. However, in experimental animals developmental anomalies appear to have been produced when steroids are given during pregnancy. Although this is not known to occur in man it perhaps sounds a note of caution. It seems very unlikely that any other complications will ensue on the dosage mentioned. At the same time it is questionable whether 5 mg. of prednisolone daily would have very much effect on the eczema. Eczema is subject to spontaneous remissions and relapses, and it may well be that the patient mentioned is now in a partial remission and that the prednisolone is not really having much effect. In the circumstances, therefore, the prednisolone might be stopped and resumed at the same dosage only if it is quite clear that the patient's condition has materially deteriorated as a consequence. The effect of pregnancy on eczema is variable and usually unpredictable. Some patients improve, some get worse, and the majority are not affected.

Sequestrene

Q.—Is sequestrene as good in laboratory work as Wintrobe's double oxalate? May sequestrenized blood be used for all those investigations for which blood anticoagulated by Wintrobe's method may be used?

A.—Sequestrene (E.D.T.A.) is at least as good in laboratory work as Wintrobe's double oxalate and for certain purposes rather better. Blood in sequestrene can be used for all those investigations for which Wintrobe's oxalate mixture is normally used.

The main advantage of sequestrene is its ability to preserve the cellular elements of the blood for a longer period than is possible with the double oxalate mixture.¹ If the than is possible with the double oxalate mixture.¹ If the correct amount of sequestrene is used, there are no obvious morphological changes in the white cells up to 4-5 hours after collection of the blood. Total red and white cell counts may be carried out up to 24 hours after collection of the blood. Sequestrene is a particularly good anticoagulant for platelets not causing any appreciable clumping or disintegration, allowing platelet counts to be made up to 6-8 hours after collection of the blood. As it is non-toxic, sequestrene is also a suitable anticoagulant for fresh blood transfusions of platelets.

Two salts of ethylene-diamine tetra-acetic acid have been used as anticoagulants—the disodium salt has been more widely used, but the dipotassium salt is probably better owing to its greater solubility (seven times as great in water.)² Both salts of E.D.T.A. may be used in a similar way. For routine haematological procedures the salts are best used in the dry form. A 10% solution in distilled water is prepared, 0.1 ml. is placed in tubes or bottles marked at 5 ml. The solution is allowed to dry at room temperature, giving 5 mg. of E.D.T.A. in each bottle, which is sufficient for 5 ml. of blood. The bottles should not be placed in a hot-air oven to dry, as this tends to make E.D.T.A. relatively insoluble. The other way to use sequestrene is as a 3% solution in 0.7% sodium chloride solution, when 0.5 ml. is sufficient to stop 9.5 ml. of blood from clotting.

Hypertrophy of Prostate

Q.—What is the present view on the aetiology of the hypertrophy of the prostate, and what are the earliest and average ages of its manifestation?

A.—The consensus of opinion is that hypertrophy of the prostate is due to hormone imbalance, but much experimental work and many therapeutic trials have given inconclusive results as to the exact mechanism.¹ Other theories that it is due to neoplasia, arteriosclerosis, or inflammation contain too much conflicting evidence to be tenable. Both histological and clinical evidence shows that the changes in the gland begin at about the age of 40 and are maximum at about 60. Within the past year two patients aged 42 have been seen with retention due to prostatic hypertrophy, but this is most uncommon and the clinical manifestations of the condition are most frequent from the age of 60. The changes may continue or the condition may remain stationary. Schinz and Reich² have shown from mortality statistics that there is a true age predisposition to the disease. Franks³ found from necropsy material that 80% of men over 80 years old had prostatic enlargement. The need for surgical as opposed to conservative treatment depends on the obstructive changes produced in the kidneys and on the amount of inconvenience or loss of sleep caused by nocturnal micturition.

Cruikshank's Hypothesis

Q.—Apart from statistical evidence, has any bacteriological, virological, or animal experimental evidence been found or sought in favour or refutation of Cruikshank's hypothesis?

A.—Cruikshank's statistical studies suggested to him that, as the mortality from pulmonary tuberculosis falls and the number of individuals with arrested tuberculosis rises, the mortality rate from lung cancer will also rise. To account for this he enunciated the purely speculative hypothesis that the body of the tubercle bacillus contains a series of carcinogenic phages and that destruction of bacilli in the lung will liberate these carcinogens, which eventually induce lung cancer. The tubercle bacillus has been exhaustively investigated and no claim has been made that it contains a bacteriophage, but there are no reports that an exhaustive but unsuccessful search for a specific bacteriophage has been made.

Operation Stockings

Q.—Are those long woollen stockings, known as operation stockings, now considered necessary?

A.—Although long woollen stockings are still widely used there is no doubt that they are quite unnecessary at the time of operation. Fashion and tradition die hard in medicine, and this is particularly true of some routine nursing procedures. The ritual use of purges and enemas took many years to expunge, and even to-day these practices are kept alive in some hospitals. The abolition of operation stockings may take as long.

The long stocking was mainly introduced as an anti-shock measure in the era when we thought it right to keep patients as warm as possible. Our views on shock have changed a good deal in the last decade or two, and it should now be recognized that these stockings are not only unnecessary but frequently positively objectionable. They are unnecessary because a patient confined to bed in a warm hospital ward, or transferred to a properly prepared

theatre trolley, should certainly not suffer from cold feet. They are objectionable because they commonly carry pathogenic organisms from the ward into the operating theatre. Ordinary laundering of woollen stockings tends to spread pathogenic organisms between the various articles and does not sterilize them. If stockings are autoclaved or boiled they will, of course, shrink badly. If surgeons insist on using such stockings, then they should equally insist on having them sterilized, and this can be done in formalin vapour without damage to the wool. Alternatively, stockings can be made of other materials which are resistant to autoclaving.

Salt and Hypertension in the Tropics

Q.—Should an elderly man with some hypertension (170/110) of ten years' duration, proceeding to the tropics, take added salt in his diet to prevent heat exhaustion? He has been on a salt-reduced diet for years.

A.—In this patient the hypertension is not severe, perhaps as a result of the low-salt diet he has been taking. It would be helpful to know whether there are any hypertensive complications such as heart failure, renal insufficiency, or cerebral vascular disease. The use of salt additional to a normal diet cannot be advised, as it might precipitate heart failure and would certainly increase the blood pressure. The patient should continue with moderate salt restriction and do his best to avoid situations where excessive sweating is likely to occur over long periods, which should not be too difficult with modern facilities for cooling houses and places of work in the tropics. If appreciable chronic renal insufficiency is present, residence in the tropics is inadvisable.

Cross-Channel Swimming

Q.—What emergencies should a doctor be ready for when accompanying a cross-channel swimmer?

A.—Medical emergencies during the organized cross-channel swims have been notably absent. The obvious risk is that of drowning. This may be precipitated by exhaustion and chilling, inhalation of vomitus during seasickness (from which the swimmers do suffer), helplessness due to cramps, drowsiness due to premedication with sedative drugs, injury due to being struck by some object (including the accompanying boat), and possible separation from the boat. Artificial respiration should be given at the earliest opportunity and time should not be wasted in clinical examination of any description. The Holger Nielsen method is not only one of the most efficient, but it is the method most practicable in the cramped conditions usually present in an accompanying boat, which may possibly be pitching and rolling. Success depends on the absence of delay in starting aeration. Pure oxygen is desirable, but its administration should be left to someone other than the doctor until normal respiration has been restored. Delay in starting artificial respiration may be caused by difficulty in getting the unconscious grease-covered swimmer into the boat, but a roller towel placed under the axillae will facilitate this operation.

It should be mentioned that, although spontaneous respiration may be restored within a few minutes, the victim may remain unconscious for some hours. A careful watch should be kept on the breathing during this unconscious phase, as respiration may fail again as a result of the hypoxia due to the gross pulmonary oedema which accompanies near-drowning.

Chilling may be sufficiently severe to cause retirement. The swimmer should be dressed as quickly as possible in woollen clothing and an outer windproof garment. Exercise and an ample supply of a hot drink—tea or coffee—are the therapeutic procedures. Degreasing should be left until later. Cramp may be severe and painful. Warmth and physiological rest are necessary; morphine is rarely likely to be required. Retention of urine and distension of the bladder may occur in those who float on their backs for long periods in cold water. This has been observed experi-

mentally in association with the greatly increased urine output in these circumstances, but it has not been reported in Channel swimmers.

The equipment bag should contain the obvious dressings for minor surgical treatments. Salt-water conjunctivitis can scarcely be described as an emergency, but it does occur, and room might be found for a dropper and a bland lotion or liquid paraffin. If it is intended to provide any anti-seasickness remedy it would be advisable to make sure beforehand that the competitor has no idiosyncrasy to whatever preparation is used. Except for a roller towel, no special items which common sense does not suggest need be carried in the emergency bag. But the value of the towel cannot be overstressed.

NOTES AND COMMENTS

Steroid Therapy and Resistance to Infection.—Professor D. A. LONG (Pittsburg, Pennsylvania, U.S.A.) writes: In reply to the question, "Is resistance to colds and other infections reduced during corticosteroid therapy?" ("Any Questions?" May 17, p. 1191), your expert states, quite correctly, that in experimental animals steroids may convert a trivial infection into a malignant one, but that in practice the risk of doing so in man is slight. Indeed, the dose of steroid should be increased during infection. He implies that the reason for this rather paradoxical state of affairs is that there is no relationship in terms of dose per kg. between the therapeutic dose in man and that required to cause septicaemia and death in animals. This is not true. The explanation for this difference is important, and indeed vital, to an understanding of research in this field and to future research on this subject. Rats, mice, and rabbits infected with bacteria and treated with corticosteroids develop overwhelming infections and die. Rhesus monkeys and guinea-pigs do not. These species may be termed "cortisone-sensitive" and "cortisone-resistant." Man belongs to the latter group and shares with them several important interrelated analogous features. The evidence for these statements has been reviewed in a recent paper.¹

REFERENCE

¹ Long, D. A., *Int. Arch. Allergy*, 1957, 10, 5.

Halitosis.—Dr. L. MCGOLRICK (Dublin) writes: Your expert's reply ("Any Questions?" July 12, p. 117), in common with many other annotations I have seen on this subject in the past, has failed to point out what I consider to be the most common cause of this embarrassing complaint in subjects whose dentition is perfect and who have neither naso-oral sepsis nor pulmonary nor gastro-intestinal disease. That is the presence of minute fragments of putrefying protein material persisting between the molars, usually the upper. These resist removal in many cases even by the most meticulous brushing, and the only remedy is the routine use of dental floss, "stimulents," or the non-U toothpick. An occasional exploration with the latter and the presentation of the result to the olfactory organ will offer a surprise and explanation to those who find their best friends averting their faces on occasions.

Collected Articles from the "British Medical Journal"

Since it was introduced in 1921 the potential dangers of insulin in the treatment of diabetic (Joslin, Root, White, and Marble, 1952) and psychiatric patients (Rees, 1949) and in diagnostic tests upon insulin-sensitive subjects such as those with hypopituitarism or Addison's disease have become well recognized. Deaths are known to have occurred in such patients as a result of accidental overdosage with insulin. Blotner (1954), in a comprehensive search of the literature, found eight recorded cases of attempted suicide by means of insulin and cases of attempted suicide by means of insulin. The present hand knowledge of the effects of insulin. The present account describes the medical and scientific investigations in a case (Regina v. Barlow) in which a man was convicted of murdering his wife by injecting her with insulin. So far as we are aware, this is the first occasion on which such a charge has been substantiated and also the first in which insulin has been demonstrated in human tissue, other than the pancreas, after death.

Outline of the Case

On Friday, May 3, 1957, Mrs. E. B., a woman of 30 years, returned home from her work in a laundry for her midday meal. At about 11.20 p.m. on the same day she was found dead in the bath, which was empty when the police arrived.

The body, which was left undisturbed until seen by the pathologist at 3.30 a.m. on May 4, lay on its right side in the empty bath with the right leg drawn up so that the right knee rested against the side of the bath and the right foot lay beneath the left knee, which was slightly flexed. The arms were bent so that the hands lay in front of and slightly below the face; the fingers of the right hand were loosely curled round the left wrist and the left hand was closed. The position of the body as a whole was one associated with natural sleep. Blood-stained froth ran from the nose down the right side of the face on to the right hand. On retraction of the eyelids it was noted that the pupils were widely dilated, and the colour of the iris, which was only discernible as a faint line round the pupil, could not be determined. In the hair, which had settled on the side of the bath, were fragments of vomited food which were also found on the sides and bottom of the bath. Caught in the crook of the right elbow were 110 ml. of clean warm water. The skin was damp where it came in contact

with the surface of the bath, the bottom of which was also damp. The body was beginning to cool and rigor mortis was developing. The face was cyanosed and there was hypostasis on the right side of the body corresponding to the position in which it was lying. There were no obvious signs of violence, and the only other things in the bath were a wet face-cloth, a tablet of carbolic soap, and a soap-dish which lay together beneath the right loin and thigh.

The police, who searched the small semi-detached house in which the body was found, noted that the walls of the bathroom were dry and that there were no signs of splashing on the floor. In the hand-basin were two pillow-cases soaking in water and stained with vomit. In the main bedroom were some lady's sweat-soaked pyjamas, and a man's dressing-gown and pyjamas which were quite dry; one side of the double bed was disturbed as though someone had lain on it. In the kitchen downstairs were found a pair of vomit-stained sheets in a washtub, two hypodermic syringes, one of which was wet, four hypodermic needles, and many drugs, including quinine. No insulin or insulin phials were discovered.

The history, as obtained by the police from the husband, was that after her midday meal of fish and chips the deceased woman had done some housework and washing. At about 5 p.m. she had her tea, which consisted of toast, grapefruit, bread, butter, and tea with sugar, and then retired to bed at 6-6.30 p.m. At 7.30 p.m. she had asked to be called so that she could watch a television programme, but, in the event, she felt "too comfortable to move" and remained in bed; she had by this time changed into her pyjamas. At 8 p.m. her husband took her a drink of water; she was then "too tired" to say good night to her stepson. At 9.20 p.m. she called to her husband, who came upstairs and found that she had vomited on the bed. Having changed the bedclothes, he also retired to bed, whilst his wife, who complained that she was "feeling too warm," lay on the bed. Later she removed her pyjamas in the bedroom and went to have a bath whilst her husband remained in the bedroom reading. He dozed off to sleep, and when he woke at about 11.20 p.m. his wife had not returned. He found her submerged in the bath and apparently drowned, so he removed the plug to let the water out and then tried artificial respiration by "pressing on her abdomen." As he was unable to lift her from the bath and as his efforts at artificial respiration did not appear to have been successful, he then summoned assistance. The husband also said that his wife was pregnant.

The preliminary examination of the body described above suggested that the immediate cause of death had been

drowning. This was confirmed at the detailed post-mortem examination which was carried out at 5.45 a.m. on May 4 and is described in detail below. Specimens were taken from the body for chemical analysis, but no common poisons or abortifacients were found. A specimen of mixed heart blood, to which no preservative had been added, was shown seven hours later to contain glucose in a concentration of 210 mg./100 ml.

At this stage, three days after her death, it seemed difficult to explain why a healthy young woman should have drowned in her bath without any apparent signs of reaction to inhaled water; she lay as though asleep with no evidence of splashing or violence. It was concluded that immediately prior to her death she must have been unconscious and that the agent responsible for this had made her sweat and vomit and had produced the gross dilatation of the pupils. These observations suggested that the deceased woman may have been hypoglycaemic. The glucose concentration in the heart blood appears to contradict this hypothesis, but, as discussed later, such an observation has little value as an indication of the glucose level in the blood during life. The detailed post-mortem examination revealed no evidence of any disease which would suggest that the woman had become hypoglycaemic spontaneously, and the possibility that she had been injected with insulin was therefore considered.

On May 8 the body, which had lain on a mortuary slab at room temperature in mild weather conditions, was again examined. On this occasion and under better lighting conditions four hypodermic injection marks were found, two in each buttock just behind the greater trochanters. The tissues underlying these marks were therefore excised and it was shown, as described below, that they contained insulin in large amounts (84 units in 170 g. of tissue). The distribution of insulin was uneven, there being more in the left buttock, which was the site of the most recent injection mark, than in the right, and more in the superficial than in the deep tissues of the left buttock. The large amount found and the uneven distribution indicated that its presence was not the result of endogenous secretion. These findings, together with control experiments described briefly below, indicated that at the time of death the buttock tissues had contained at least 240 units of insulin. Such a dose must have been sufficient to produce either the soporific or comatose stages of the hypoglycaemic state (see Rees, 1949). No insulin was found in washings from the wet hypodermic syringe or needles.

On July 26 the husband of the deceased woman, a trained male nurse, was arrested and charged with the murder of his wife. He denied having injected insulin, but explained the presence of the injection marks by stating that on several occasions he had injected his wife with ergometrine maleate in therapeutic doses during the two weeks preceding her death in an attempt to procure abortion; he said he gave the last injection after the midday meal on the day of her death. The actions of this drug do not explain the signs and symptoms found in this case, and analysis of the urine and part of the buttock tissues did not reveal its presence.

The trial took place before Mr. Justice Diplock at Leeds Assizes in December, 1957, and the accused man was found guilty and sentenced to life imprisonment.

Post-mortem Examination

Two examinations were made; the first about six and a half hours after the body was found, and the second about four days later. On the first occasion artificial strip lighting with a bluish tinge was in use, and this was known to make identification of minute haemorrhages difficult. No such difficulty was encountered on the second occasion in bright daylight.

First Examination (5.45 a.m., May 4)

The body was that of a very well nourished young woman 5 ft. 3 in. (160 cm.) tall and proportionately built. The face

was cyanosed and the hypostasis was not fixed. The skin on the palms of the hands and soles of the feet was sodden, whilst elsewhere there were moles, freckles, and acne spots. Blood-stained froth issued from the nose, and petechial haemorrhages were found beneath the conjunctivae, the blood vessels of which were suffused with dark blood. No external evidence of violence was detected at this stage.

Internally the nose, mouth, and air passages contained blood-stained froth. The lungs were very bulky, congested, and wet; froth could be expressed from the smaller air passages, and subpleural petechial haemorrhages were found. The heart was apparently healthy, but was dilated on the right side, which was full of dark fluid blood. The uterus contained a normal foetus of about eight weeks' gestation with unruptured membranes; the cervix was healthy and a mucus plug was present. Petechial haemorrhages were found in the sheaths of the temporal muscles, and the meningeal vessels contained dark fluid blood. Routine examination of all other organs disclosed no abnormality other than that associated with acute venous congestion. No macroscopic evidence of disease was found in the pancreas, pituitary, thyroid, or suprarenal glands.

Histological examination of the lungs revealed oedema, small haemorrhages, and acute emphysema. The brain and spinal cord showed vascular engorgement and small haemorrhages. The heart muscle was normal. Vascular engorgement and some cloudy swelling were noted in the liver, spleen, and kidneys.

Bacteriological examination revealed no pathological organisms in the intestinal contents or the spleen.

It was concluded that death probably occurred between 5 p.m. on May 3 and 1 a.m. on May 4, the narrower limits being between 10 and 11 p.m. on May 3; that death was caused by asphyxia due to drowning; and that at the time of her death the deceased was probably under the influence of a drug.

Second Examination (9.15 a.m., May 8)

With the aid of a hand-lens four possible hypodermic injection marks were found, two lying close together on each buttock about 2 in. (5 cm.) behind the greater trochanters. One mark on the left side appeared to have a red track in the skin almost at right angles to the surface of the body and a small area of fat necrosis was found about 1-1½ in. (2.5-4 cm.) from the surface; these findings were confirmed microscopically. One of the marks on the right side also showed a doubtful vertical red track in the skin and, microscopically, a slight inflammatory reaction was found in the underlying fat. It was concluded that one mark in the left buttock was comparatively recent and had been produced a few hours before death, whilst one on the right buttock was slightly older.

A piece of skin, fat, and muscle (178 g.) including the hypodermic marks was excised from the right buttock; this is subsequently referred to as Sample R. A similar piece of tissue (131 g.) was cut from the left buttock (Sample L), but as this did not appear to include as much muscle as the sample from the right buttock a further piece (62 g.) of deep muscle (Sample DL) was excised. These pieces of tissue were stored without addition of any preservative in a refrigerator at about 4° C. for 15 days, after which they were examined, as described below, for their insulin contents.

Chemical Analysis

At 11 a.m. on May 4 a standard routine toxicological analysis was begun on specimens removed from the body at the first post-mortem examination. This analysis consisted of a search for several hundred poisons and drugs (including, *inter alia*, procaine, ergometrine, and quinine), and also certain biochemical investigations such as the measurement of the glucose content of the mixed heart blood and analysis of the urine for sugar and acetone. Specimens of vomit and of stomach and intestinal contents were examined separately, and 500-g. aliquots of liver and brain were analysed for the presence of poisons which might

have been injected; details of this routine analytical procedure will be published elsewhere (Curry, 1958a, 1958b). Nothing abnormal was found.

Traces of procaine penicillin were found in one of the hypodermic needles. In view of this, and because of the statement by the accused that ergometrine maleate had been injected into the deceased woman some hours before death, tests capable of detecting 1 µg. of ergometrine or procaine in buttock tissue were applied to samples (approximately 60 g.) of the buttock tissue. No evidence of either alkaloid was found. Had she received a therapeutic dose of ergometrine seven hours before death, the alkaloid would have been detectable in as little as 5 ml. of the urine; in fact, none was found in 35 ml.

Tests capable of detecting the phenolic preservatives present in 0.2 ml. of commercial insulin solutions were also applied to the samples of buttock tissue. The results of these tests were not conclusive, but, since these substances rapidly disappear from the injection site, they suggest that the injections had been made some time before death occurred.

Because injections of insulin preparations containing added zinc do not appreciably increase the zinc content of tissues, analysis for zinc would not have been of any value in identifying the type of insulin used.

Blood-sugar Concentrations after Death

The glucose concentration in a sample of mixed heart blood taken from the body of the deceased woman about six hours after death and examined seven hours later, after storage without addition of preservative, was found to be 210 mg./100 ml. Urine taken at the same time contained neither glucose nor ketone bodies. The latter finding excluded the possibility that the woman was diabetic and in a hyperglycaemic coma at the time of her death, but the high blood-sugar level did not support the hypothesis that she had been hypoglycaemic.

It is known that the glucose concentration in the blood on the right side of the heart may rise for a period after death (Hamilton-Paterson and Johnson, 1940; Hill, 1941). This rise, often most marked in well-nourished subjects after asphyxial death, is due to glycogenolysis in the liver and subsequent diffusion of glucose into the inferior vena cava and the right heart. On the left side of the heart the glucose concentration usually falls progressively owing to glycolysis by the blood cells.

In 38 non-diabetic subjects, most of whom had died sudden or violent deaths, these observations were confirmed. The glucose concentration in blood drawn from the right side of the heart ranged from 20 to 671 mg./100 ml. and side of the heart ranged from 20 to 671 mg./100 ml. That was frequently much greater than 210 mg./100 ml. This rise was due to release of glucose from the liver after death was shown by the fact that it could be prevented if the inferior vena cava was ligated. The glucose level in the inferior vena cava was lower than that blood from the left side of the heart was lower than that on the right side and ranged from 18 to 180 mg./100 ml.; if any rise occurred it was minimal (not more than 10 mg./100 ml.), and on one occasion only was a high level (440 mg./100 ml.) found.

In one case, that of a woman who committed suicide by drowning herself in a bath, a sample of mixed heart blood taken 29 hours after death contained glucose in a concentration of 355 mg./100 ml. The glucose levels in blood taken from the right heart (44 mg./100 ml.), inferior vena cava (56 mg./100 ml.), and left heart (50 mg./100 ml.) of another subject five hours after a slow death were low and approximately equal; 12 hours later the levels in the right heart (120 mg./100 ml.) and inferior vena cava (343 mg./100 ml.) had risen, while that in the left heart remained low (60 mg./100 ml.).

It is apparent that many factors, such as the glycogen content of the liver and coagulability of the blood, affect the degree and speed of the changes that occur in the glucose content of the blood after death. It is also apparent

that the high glucose content of mixed heart blood taken from the dead woman in the case described here does not exclude the possibility that she was hypoglycaemic before death.

Detection, Assay, and Identification of Insulin in Tissues

Although the structure of insulin, a protein of small molecular weight, is now known (Ryle, Sanger, Smith and Kitai, 1955), no chemical or physico-chemical method has yet been devised for its identification when mixed in small amounts with other tissue proteins. The only method available for identification and assay of insulin in the present case involved its extraction from the tissues in a crude form and examination of the biological activity of the extract. Chromatographic methods of separation were investigated and yielded some confirmatory evidence. A detailed account of the technical methods employed will be published elsewhere.

Extraction of Tissues

Crude extracts were prepared from the tissue samples by an improved method based on that originally described by Fisher and Scott (1934). By this method insulin is extracted irrespective of whether it is present as soluble insulin or in the form of one of the delayed-action preparations such as protamine zinc insulin or insulin zinc suspension. To assist in the identification of the insulin, portions of some of these extracts were further purified by a method similar to that described by Dodds and Dickens (1924); in this way a fourfold increase in insulin concentration was obtained.

After removal from the body four days after death the specimens of tissue were stored at 4° C. for 15 days, and subsequently at -20° C. until extracted. Extracts R, R₂, L, L₂, and DL were prepared from aliquots of the corresponding tissue samples.

In addition, many experiments were done on human tissue obtained at necropsy. Over 20 pieces of buttock tissue were removed from cadavers of both sexes, including a female drowned in a bath, and extracts prepared either immediately or after preliminary storage under conditions similar to those used for the tissues of the deceased woman; none of these extracts showed hypoglycaemic activity. Other pieces were injected with soluble insulin or protamine zinc insulin and then extracted immediately or after storage. It was shown that insulin could be recovered by the extraction method and that a considerable proportion of any insulin present in buttock tissue survives under the conditions of storage to which the specimens from the dead woman had been subjected. Although it is impossible to be precise, the control experiments suggested that about two-thirds of the insulin present in the injected tissue was recovered by extraction and that roughly half of the insulin originally injected survived the period of storage; these conclusions apply both to soluble insulin and to protamine zinc insulin. It was also shown that extracts of cadaver tissue injected with ergometrine exert no hypoglycaemic effect; nor does its presence modify the effect of insulin injected simultaneously.

The only control extracts mentioned in this account are extract E, prepared from buttock tissue removed from a fresh cadaver, and extract F, prepared from tissue (from the same cadaver) into which a known amount of soluble insulin had been injected.

Biological Activity of Extracts

Hypoglycaemic Action in Mice.—The mouse convulsion method of insulin assay described in the *British Pharmacopoeia* (1953) was employed; the results are shown in Table I. The activity in the extracts from 170 g. of tissue from both buttocks was equivalent to a total of 84 units of insulin. The uneven distribution in the two buttocks is clearly seen from Table I; widely differing concentrations were also found in two extracts (R and R₂) from

and the police officers assigned to the case; the directors of Boots Pure Drug Co. Ltd., Nottingham; Dr. D. K. Bruce, medical superintendent, Storthes Hall Hospital, near Huddersfield; Professor C. S. Russell, department of obstetrics and gynaecology, Sheffield University; Professor R. H. S. Thompson, department of chemical pathology, Guy's Hospital Medical School; and Mr. T. Dean, consultant obstetrician and gynaecologist, Barnsley Group of Hospitals.

CASE FOR INDUCTION OF LABOUR IN TREATMENT OF HAEMOLYTIC DISEASE OF THE NEWBORN

BY

G. A. KELSALL, M.B., Ch.B.

G. H. VOS

King Edward Memorial Hospital for Women, Subiaco, Western Australia

AND

R. L. KIRK, M.Sc.

Zoology Department, University of Western Australia

In a series of papers in the *British Medical Journal*, Walker and his colleagues have reported their experience in the management of cases of haemolytic disease of the newborn (Walker and Murray, 1954, 1956; Walker, Murray, and Russell, 1957; Walker and Neligan, 1955). Their analysis has been based largely on a series of cases referred for treatment in the Newcastle United Hospitals and in other centres in N.E. England during the past ten years. The management of the cases reported in those studies has been modified in the light of experience, so that the earlier reports refer to methods of treatment rather different from those used currently.

In the initial studies Walker and his colleagues subscribed to the view that the induction of labour had no place in the treatment of the infant suffering from haemolytic disease of the newborn. This view was based largely on the results of a clinical trial which suggested that prematurity greatly increased the risk of death in affected infants (Mollison and Walker, 1952; Armitage and Mollison, 1953). More recently, however, the Newcastle group has suggested that induction of labour should be used in cases where an Rh-immunized mother has already had a stillbirth due to

Rh incompatibility in a previous pregnancy. This suggestion has been incorporated in the second edition of *Blood Transfusion in Clinical Medicine* (Mollison, 1956). Subsequently, as a result of a study of the influence of the father's genotype on the severity of haemolytic disease in the affected infant, Murray (1957) has suggested that induction of labour might be justified also in cases where the father is shown to be R_2R_2 (cDE/cDE), since the risk of stillbirth in such cases, according to her analysis, is much greater than if the father is of any other Rh genotype.

In contrast to the views of the English workers, we have during the past seven years consistently advocated the use of induction of labour as an integral part of the treatment of Rh cases where the antenatal indications suggest that the infant will be severely affected. We believe that the time is now ripe to attempt a detailed comparison of the work of both the English group and our own.

Criteria of Severity

Indications for Exchange-transfusion

Walker and Murray (1954), as a result of several years' experience, have adopted the following criteria for determining the need for exchange-transfusion: "A Coombs-positive baby with a cord Hb level of 14.8 g.% or less, and a cord Hb level of 14.9 to 17.7 g.% associated with a bilirubin level greater than 2.7 mg. per 100 ml. . . . In those cases in which the cord-blood samples were not ideal we have been guided by whichever result was available. In practice this has usually been the cord bilirubin level, and we have treated any infant with a value greater than 2.7 mg. per 100 ml. . . . If cord-blood values were not available we have relied on clinical criteria."

Our practice during the past six years has been to rely upon the antibody level in the maternal serum as determined by a carefully standardized indirect antiglobulin method (Kelsall and Vos, 1952; Watson and Vos, 1952; Kelsall, Vos, Kirk, and Shield, 1957). No baby receives treatment if the maternal indirect antiglobulin titre at term is 1/64 or less. On the other hand, we exchange-transfuse all infants where the maternal indirect antiglobulin titre at term is higher than 1/128. Our original procedure was to transfuse all infants where the maternal titre at term was 1/128. We have found more recently, however, that some infants in this category with a high cord-blood haemoglobin value and no excess antibody free in the cord serum can safely be left alone.

Indications for Induction of Labour

In order to justify the premature termination of a pregnancy some reliable criterion must be available for predicting the severity of the disease in the infant. Since at the present time no complete certainty is associated with any of the criteria used for assessing severity in Rh cases we have to rely on a statistical evaluation of whatever criterion is being considered.

Walker and Murray (1956) have shown that when a mother has had one or more stillborn infants due to Rh incompatibility the chance of stillbirth in the next Rh-positive pregnancy is approximately 80%. A previous stillbirth is suggested, therefore, as a sufficiently reliable indication to justify induction of labour in the next pregnancy.

This criterion of severity, though perfectly valid, has the disadvantage that the mother must experience at least one stillbirth in order to provide the yardstick for prognosis in the next pregnancy. In addition there are many cases where the mother has had a seriously affected but surviving child in which the chances of a stillbirth in the next pregnancy are quite high. Walker and Murray have shown for their own series that if the previous baby was very severely affected the chance of a stillbirth is almost as high as when the previous pregnancy ended in a stillbirth, and that even when

the previous baby was severely affected the chance of a stillbirth is still 25%. In a more recent but still preliminary study Walker (1957) has explored the use of spectrophotometric analysis of samples of amniotic fluid obtained by abdominal paracentesis. He reports that specimens obtained at the 32nd week of pregnancy can be used to forecast correctly an affected child in approximately 90% of cases, and suggests that this method may be of value in discriminating between an Rh-negative and an Rh-positive foetus in cases where a woman married to a heterozygous husband has had a previous stillbirth.

We believe that it is desirable to use a criterion of severity which is applicable in the absence of a previous stillbirth and also during the first pregnancy in which Rh antibodies are present in the mother. For this reason, since 1950 we have assessed the need for induction of labour, as we have the need for exchange-transfusion, using the indirect antiglobulin titre of the maternal serum. Our practice in general is to recommend induction at the 35th or 36th week of pregnancy when the maternal antiglobulin titre is at 1/512 or higher, and at the 37th or 38th week when the titre is at 1/128 or 1/256. A maternal titre of 1/64 or less does not merit the artificial termination of pregnancy.

Reliability of Antiglobulin Titre as a Prognostic Index

From October, 1951, to April, 1957, we have observed 429 infants which have resulted from 421 consecutive pregnancies where Rh antibodies were detected in the mother's serum. A further series of 69 cases between January, 1950, and October, 1951, have been analysed in part previously (Kelsall and Vos, 1952). These early cases were accumulated during the exploratory period in this investigation; treatment was not consistent throughout, and they have therefore been excluded from the present discussion. Kelsall *et al.* (1957) have analysed in detail the first part of the series of cases reported here.

From October, 1951, we have attempted to follow our standard rules for the management of the cases as closely as possible, although we have not always been able to do this. All antibody titrations have been carried out in the same laboratory, using the same procedure, and 96% of the exchange-transfusions have been performed by the same operator (G. A. K.). All cases have been included where an antiglobulin titration of the mother's serum was carried out either on the day of birth or within two or three days prior to birth and where the pregnancy continued for at least 20 weeks. In 265 cases weekly or fortnightly antiglobulin titrations were carried out over at least the last ten weeks of pregnancy; 43 of these pregnancies resulted in Rh-negative infants. In the remaining cases, for various reasons, titrations could be carried out only sporadically throughout pregnancy, or near term.

Of the total of 429 infants, 56 (13.0%) were Rh negative. Of the remaining 373 incompatible infants, 65 (17.4%) were stillborn and 308 (82.6%) were liveborn. Thirty-four of the stillborn infants (9.1% of the incompatible infants) subsequently died, 20 of them despite prompt and adequate exchange-transfusion. The other 14 were untreated, death

TABLE I.—Distribution of 373 Cases of Incompatible Infants Born to Rh-immunized Mothers from October, 1951, to April, 1957, by Maternal Indirect Antiglobulin Titre at Term

Maternal Titre at Term	No. of Cases	Liveborn Rh+ Infants		Stillbirths	% Foetal Wastage
		Survived	Died		
1/64 or less	60	59	0	1*	1.7
1/128	30	28	1	1†	6.7
1/256	60	53	5	2	11.7
1/512	70	62	4	4	11.4
1/1,024	82	46	9	27	43.9
1/2,048 or over	71	26	15	30	63.4
All titres	373	274 (73.5%)	34 (9.1%)	65 (17.4%)	

* Mongol. † Anencephalic monster.

having supervened before exchange-transfusion could be started. Four of these untreated infants were of 30 weeks or less gestation.

Table I shows the distribution of these cases by the indirect antiglobulin titre of the mother's serum at term. The foetal wastage from all causes rises from 1.7% where the maternal titre is 1/64 or less to 63.4% where the titre is 1/2,048 or higher. Infants born to mothers with titres of 1/64 or less, with the exception of four cases, received no treatment. All viable infants, with the exception of 13 cases, born to mothers with titres of 1/128 or higher were exchange-transfused. The four cases which were exchange-transfused where the maternal indirect antiglobulin titre at term was 1/64 or less were transfused because of over-anxiety by the patient's doctor. There is nothing to suggest that they would not have survived normally if they had been left untreated.

Almost all of the foetal wastage in this series occurred in cases where the maternal antiglobulin titre at term was 1/512 or higher. The remaining cases, although indicating that stillbirth or neonatal death may occur where the maternal titre is lower than 1/512, have to be considered in the light of the actual causes of death. Of the four stillbirths in the lower-titre categories, two at least were not due primarily to Rh incompatibility, one being a mongol and the other an anencephalic monster. There were six neonatal deaths in the same titre categories. One of these was of only 29 weeks' gestation, was untreated, and died primarily of prematurity; another died at the age of 4 days with an obstruction of the duodenum, whilst one died at home aged 3 weeks, the diagnosis of the cause of death being septicaemia. Thus of the 10 cases where a stillbirth or a neonatal death resulted if the mother had an antiglobulin titre at term of less than 1/512, only five were due primarily to Rh incompatibility. This means that in this series, with our methods of treatment, 95% of the foetal wastage due to Rh incompatibility occurred in mothers with an indirect antiglobulin titre at term of 1/512 or higher.

Any criterion of severity based on neonatal wastage will be dependent on the effectiveness of the exchange-transfusion therapy. If no therapy had been given the number of deaths would have been much higher. It is possible, however, to test the value of indirect antiglobulin titre at term as a measure of severity in another way. We have shown previously (Kelsall *et al.*, 1957) that there is a highly significant

TABLE II.—Relationship Between Maternal Indirect Antiglobulin Titre at Term and Cord-blood haemoglobin values for Rh-positive Infants Born to Rh-immunized Mothers

Cord-blood Hb (g./100 ml.)	No. of Cases at Maternal Titre of:						All Titres
	1/64 or Less	1/128	1/256	1/512	1/1,024	1/2,048 or Higher	
18.0 and over	7	1	3	4	1	1	11
16.0-17.9	11	7	6	16	9	3	30
14.0-15.9	24	9	23	18	8	3	84

Total	50	24	53	55	49	35	266
Not available	9	5	5	11	6	6	42

correlation between the maternal indirect antiglobulin titre at term and cord-blood haemoglobin values ($r = -0.612$). The relationship between maternal titre and cord-blood haemoglobin for the 266 cases of the present series of live-born Rh-positive infants where the relevant information is available is shown in Table II.

Two points of interest emerge from a consideration of the distribution of these cord-blood haemoglobin values. The first is that the cases in our series are more severe than those reported by Walker and Murray (1954). For the two years 1952 and 1953, 30% of their cases had cord haemo-

globin values of less than 13.3 g. per 100 ml. In our series 53% had haemoglobin values of 13.9 g. per 100 ml. or less (44% were actually less than 13.3 g. per 100 ml.). Allowance for this difference in severity must be made when comparing either the percentage of cases requiring exchange-transfusion or the success of the treatment in the two series.

Secondly, it is clear that there is a considerable area of overlap in the infants which Walker would consider to require exchange-transfusion and those which would receive it by applying our rules. Fifty-nine of our Rh-positive infants required no treatment (although, as noted above, four of these received it) since the maternal antiglobulin titre at term was 1/64 or less. In addition treatment was withheld from a further 10 infants with a maternal titre of 1/128 largely on the basis of absence of excess antibody in the cord serum at term. In total, therefore, at least 69 out of 308 liveborn Rh-positive infants (22.0%) survived without treatment. It is interesting to note from a study of the individual Hb values that at least 29 of these had a cord-blood haemoglobin of 14.8 g. per 100 ml. or less and would have been exchange-transfused by the English workers.

On the other hand, two of our cases which were exchange-transfused had a cord haemoglobin value above 17.7 g. per 100 ml. and would not have been exchange-transfused on the English standard. In addition, 40 of our exchange-transfused cases fell into the intermediate category where a bilirubin estimation would be necessary on the English standard. We have extracted the bilirubin values from our records for the cases with cord Hb values of 14.8–17.5 g. per 100 ml. in the titre categories of 1/128 or higher. Thirty-three of these had bilirubin determinations, and 15 of them were lower than 2.7 mg. per 100 ml. in the cord serum. Thus at least 17 of our cases which were exchange-transfused would not have merited exchange-transfusion on the English standard at birth, though some of these may have required either exchange or simple transfusion later on if severe jaundice developed after birth.

It is interesting to note, therefore, that the two sets of criteria employed as an indication for exchange-transfusion—maternal indirect antiglobulin titre on one hand, and a combination of cord-blood haemoglobin and bilirubin values on the other—have about the same efficiency in predicting the need for exchange-transfusion.

Titre Level and Duration of Response During Pregnancy

Although there is a close relationship between the maternal indirect antiglobulin titre at term and the chance of having a successful outcome of pregnancy, this by itself does not mean necessarily that the early induction of labour should be carried out. If the maternal titre at 36 weeks is 1/512, it could be argued that it might remain at this level during the next four weeks. The relationship between maternal indirect antiglobulin titre at delivery and outcome shown in Table I would indicate the chance of successful outcome in such a case to be greater than 90%. But the picture obtained by considering the relationship between a single maternal indirect antiglobulin titration at term and chance of survival may be misleading. It does not indicate whether the titre determined at the time of delivery has just arrived at that level, perhaps quite suddenly from a low or zero value, or whether the foetus has been exposed to the same quantity of antibody for a considerable length of time.

In 222 of our incompatible cases antibody titrations have been carried out weekly or fortnightly during the last 10 weeks of pregnancy. This has made possible the calculation of a "titre index" to give some measure of the effect of the titre level and the duration of the response on the severity of the disease in the affected child. The titre index is calculated by multiplying the titre code number by the number of weeks and summing for the total 10-weeks period. The code numbers used range from 1 for a titre of 1/16 or less, 2 for 1/32, 3 for 1/64, etc., to 9 for a titre of 1/4,096 or higher. Thus a mother who has maintained a titre of 1/1,024 over

the whole 10-weeks period will have a titre index of $7 \times 10 = 70$. On the other hand, a mother who has a titre of 1/1,024 at term but started the 10-weeks period with a titre of 1/64 and rose progressively each two weeks up to this titre will have an index of $2 \times 3 + 2 \times 4 + 2 \times 5 + 2 \times 6 + 2 \times 7 = 50$.

The distribution of our 222 cases in four categories of titre index where this information is available is given in Table III. Where the titre index is 40 or less, as it was in

TABLE III.—Relationship Between Maternal Indirect Antiglobulin Index and Outcome of Pregnancies of Rh-sensitized Mothers. See Text for Method of Calculating the Index

Indirect Antiglobulin Index	No. of Cases	Liveborn Rh + Infants		Stillbirths	% Foetal Wastage
		Survived	Died		
40 or less	87	84	2	1*	3.4
41–60	71	54	8	9	23.9
61–70	39	16	3	20	59.0
71 and over	25	5	4	16	80.0
All indexes	222	159	17	46	28.4

* Mongol.

87 of the cases (39%), the chance of a fatal outcome is only 3.4%. The one stillbirth was the mongol referred to previously. If the titre index is between 41 and 60 the chance of a fatal outcome is 23.9%, and from 61–70 it is 59.0%. If the titre index is above 70, as it was in 25 of our cases, the chance of a fatal outcome is 80%.

On the basis of these results it is possible to estimate the increase in severity which will occur if a pregnancy is allowed to continue for any particular length of time. For example, if a mother has reached 36 weeks and has a titre of 1/1,024, and during the previous six weeks her titre score has reached 40, then even if her titre remains unchanged she will accumulate $4 \times 7 = 28$ points to give a final titre index of 68 if the pregnancy continues to full term. This means that there is almost a 50% chance that the infant will be stillborn, or, if liveborn, will be very seriously affected, with a 30% chance of death. In some of the liveborn cases death will occur before exchange-transfusion can be started. It is clear, therefore, that accurate knowledge of the maternal antibody level and its behaviour from the 26th week of pregnancy onward enables one to predict before birth the degree of severity in the affected child with a high degree of accuracy.

Two factors at present complicate the use of the indirect antiglobulin titre and index as prognostic tools, though neither reduces its value when used with care. The first complicating factor is that even though a high titre index may be obtained, owing to the persistence of antibodies from a previous pregnancy, an Rh-negative infant may result. Out of 43 cases in the present series where the outcome was an Rh-negative infant and for which a titre index was available, 5 had an index of over 60, and 17 had an index between 41 and 60. Most of these cases were induced, since, although it was known that the father was heterozygous, we could not be certain that the infant was negative. However, despite this we have no evidence that prematurity adversely affected in any way the small number of negative infants which resulted from this procedure. All but one of the induced Rh-negative infants survived and are now alive and well. The one neonatal death occurred from cerebral haemorrhage in a baby induced at 40 weeks' gestation.

The other complicating factor is the presence of severe oedema in the mother. In our hands a falling antibody titre may be associated with developing maternal oedema, and care must be taken in such a case not to conclude that the infant is Rh-negative. In Table I the neonatal death shown against the maternal titre of 1/128 illustrates this point. The mother was grossly oedematous and the infant at birth was hydropic and did not breathe. The titre of antibodies present in the cord-blood of this infant suggests that the maternal titre should have been 1/1,024. This case, however, is exceptional in our experience in the degree of reduction of the

maternal antiglobulin titre. In most cases of maternal oedema the indirect antiglobulin titre, if reduced at all, is affected by only one tube dilution, and more rarely by two. Appropriate care must be exercised, therefore, in determining the prognosis where pregnancy is complicated in this manner.

Evaluation of the Policy of Induction of Labour

If Rh-negative infants are excluded, there have been 194 infants resulting from spontaneous labours and 179 infants from induced labours in the present series (Table IV). The spontaneous group includes some that were left to proceed to term because of low maternal titres, some that went into spontaneous premature labour before induction could be started, and some that proceeded to term because they were not referred to us early enough for induction to be instituted. Among the induced group 61 (or 30% of the induced infants) resulted from pregnancies which were terminated before the 37th week.

The pregnancies which terminated spontaneously are notable for the large number of stillbirths, all but 4 of the total of 65 occurring in this group. Of the 61 spontaneous stillbirths, 48 resulted from pregnancies of less than 37 weeks, and 34 of these were from pregnancies of less than 35 weeks. Thus, of the remaining stillbirths, only 27 could possibly have been affected by inducing labour at the 35th or 36th week. Some of these, moreover, had been dead *in utero* for varying lengths of time before birth, so that only a proportion would have been born alive had they been successfully induced. It is possible that half of these may have been retrieved in this way.

There were 15 neonatal deaths in the spontaneous group. Seven of these infants were born to mothers with a titre of 1/1,024 or higher after 37 weeks' gestation. Most of these, perhaps five, could have been retrieved had they been induced at the 35th or 36th week.

Of the total of 76 stillbirths and neonatal deaths in the spontaneous group it is possible, therefore, that 25% could have been saved if induction had been carried out early, followed by prompt and adequate exchange-transfusion.

Among the 179 induced infants there were 19 neonatal deaths and 4 stillbirths. The 11 deaths and 2 stillbirths under 37 weeks group probably represent the irreducible mortality by our methods of treatment. However, perhaps four of the eight deaths in the 37 weeks and over group might have been prevented if induction had taken place one or two weeks earlier.

It is possible to make the converse calculation and estimate how the severity of the cases in the induced group would have been affected if they had all been left to go to term. There were 36 cases induced at 35 and 36 weeks for which an indirect antiglobulin index is available. If it is assumed that the titre at delivery would have persisted at the same level for another four weeks—that is, until full term—the level for another four weeks—can be recalculated by using the last six weeks of the actual pregnancy and adding the remaining four weeks. When this is done, 8 of the 36 cases would have had the antiglobulin index increased by 10 or more points. Eleven of the cases would not have changed their antiglobulin index, but since 10 of these already had an index

above 60 at the time they were induced it is most unlikely that many of them would have continued to term and produced a living infant.

The above estimate is based on the assumption that no increase in the maternal antiglobulin titre would occur between the 35th and 36th weeks and full term. In actual fact, of course, many of the titres would have risen considerably, producing a more serious prognosis in an even greater proportion of cases. Further, the same arguments would apply to those induced at the 37th–38th week of pregnancy if they had been allowed to go to full term.

If these figures are used as a guide it is possible that at least another 20 neonatal deaths and stillbirths might have resulted in our series if no induction of labour had been performed. This would have meant a total foetal wastage of 119 (31.9%) in 373 cases of incompatible infants born to Rh-immunized mothers if all pregnancies had been allowed to terminate spontaneously. In contrast to this, if we had been able to apply our rules for induction and treatment in every case in our series it is likely that the number of neonatal deaths and stillbirths would have been reduced to 76 (20.4%). On this basis we can conclude that the uniform adoption of early induction of labour in cases where the antiglobulin titre of the maternal serum indicates the need, followed by prompt and adequate exchange-transfusion, would effect an overall reduction of mortality of 11%, or, put in another way, one in every three of the foetal deaths would be saved.

Discussion

The arguments for and against the early induction of labour in the treatment of haemolytic disease of the newborn have been stated many times during the past ten years. Diamond (1947) reported the use of induction of labour, but, following the demonstration by his group that kernicterus was more commonly associated with the immature infant, its use was gradually abandoned (Allen *et al.*, 1950). More recently, however, the same group has concluded that a certain number of stillbirths can undoubtedly be prevented by premature induction of labour. They recommend induction at 37 weeks, when the conditions are obstetrically favourable and the foetus is of good size and viable (Allen *et al.*, 1954; Allen, 1957).

The main argument in England against induction of labour in the treatment of haemolytic disease rests on the analysis of a series of controlled clinical trials (Mollison and Walker, 1952; Armitage and Mollison, 1953). In the analysis of these trials a critical comparison was made between the number of deaths (including stillbirths) in a group of 77 infants resulting from artificially terminated pregnancies and 108 infants from spontaneously terminated pregnancies. Although the stillbirths were reduced in the former group the neonatal deaths were increased, so that the overall mortality was 36.4% for the induced group compared with 24.1% for the spontaneous group.

The difference in mortality, as the authors were careful to point out, was not significant at the 5% level. But they go on to conclude, on the basis of the results obtained, that induction is unlikely to improve the survival rate by more than 1%.

TABLE IV.—Outcome of Pregnancies Terminated Spontaneously or Artificially. Rh-negative Infants have been Excluded

among the patients who were considered sufficiently ill to warrant therapy, but who were not treated because they could not co-operate or lived too far away, were excluded.

It can be seen, therefore, that long-term anticoagulant therapy has reduced the mortality rate after 18 months from an expected rate of 24.3% in an unselected group of 325 patients to 11.6% in a selected group of 77 patients with severe disease. In this selected group of severe cases the percentage of patients with recurrent infarction was 66%, compared with only 19% in the unselected control series. The incidence of heart failure in the treated group was 44%, compared with 36% in the untreated control group. Had no anticoagulant therapy been given, one would certainly have expected the mortality rate in the treated group of selected severe cases to be much higher than that in the control series, to counterbalance the much lower mortality rate in the group of untreated patients who were not considered sufficiently ill to warrant therapy (Table V). The results of treatment with anticoagulant therapy are therefore better than appears from a straight comparison of the mortality rates for the treated patients (Table IV) and the control series (Table III).

Analysis of Deaths in Treated Series

A brief summary of the condition and progress of the patients who died whilst receiving long-term anticoagulant therapy may be informative.

1. Woman aged 74. Twice admitted to hospital for congestive cardiac failure and coronary thrombosis. After third admission to hospital for second attack of coronary thrombosis complicated by arterial embolism of the leg, long-term anticoagulants started, but patient died at home six weeks after discharge from hospital. Was not under adequate anticoagulant cover at time of death. No necropsy.

2. Man aged 75. Long-term anticoagulants started after second episode of coronary thrombosis. Patient in persistent severe congestive cardiac failure with grossly enlarged heart. Developed retention of urine from an enlarged prostate, for which suprapubic cystotomy needed whilst patient was on anticoagulants; was not fit to undergo prostatectomy, being practically bedridden throughout. Died after ten months' treatment; anticoagulants stopped one week before death. Necropsy showed whole of left ventricle replaced by shell-like aneurysm of muscle wall. Death due to heart failure with no evidence of recent infarction.

3. Woman aged 76. Attack of coronary thrombosis four years previously. Long-term anticoagulants continued after recurrence of infarction accompanied by severe congestive cardiac failure, which persisted throughout her illness. Grossly enlarged heart and auricular fibrillation present. Died after three months' treatment. Necropsy showed an old but no recent infarction, death being due to cardiac failure.

4. Man aged 81. Anticoagulants continued after severe attack of thrombosis accompanied by shock, hypotension, cardiac failure, and heart block. Heart greatly enlarged. Remained remarkably well and active, with few signs of cardiac failure for 12 months. He then developed severe cardiac failure and auricular fibrillation. Anticoagulant therapy, which had been under excellent control, became unstabilized, presumably because patient was not able to co-operate; he lived alone. Found dead at home; was presumed to have been dead for four days before being discovered. Coroner's post-mortem examination gave the cause of death as cardiac failure and coronary thrombosis.

5. Man aged 66. Long-term anticoagulants continued after his second coronary thrombosis. He had also been treated in hospital on four occasions for chronic bronchitis. Twice admitted to hospital for bronchitis and cardiac failure whilst on anticoagulant therapy. Developed recurrence of cardiac failure and died in hospital 13 months after starting anticoagulant therapy. Necropsy showed almost totally occluded coronary arteries from advanced atherosclerosis with greatly enlarged heart. No recent thrombus discovered in vessels, but section of myocardium reported as organizing infarct present in muscle with multiple old infarcts.

6. Man aged 64. Treated for hypertension for several years with blood pressure 230/140 and heart grossly enlarged with cardiac failure present. Long-term anticoagulants continued after first attack of coronary thrombosis and also treated with hypotensive drugs. Required admission to hospital on three occasions whilst on anticoagulant therapy for treatment of cardiac failure. Died quietly in his sleep at home 14 months after starting treat-

ment. Necropsy was not held. Anticoagulant therapy was not easy to control, and patient was thought to have had inadequate anticoagulant cover.

7. Man aged 63. In hospital on three occasions for two attacks of coronary thrombosis and basilar artery insufficiency. The blood pressure was 220/120, with a grossly enlarged heart. Patient developed cardiac failure with second attack of thrombosis. Collapsed at a football match and died shortly afterwards, 14 months after starting long-term anticoagulant therapy. Coroner's post-mortem examination reported cause of death as coronary thrombosis.

8. Man aged 61. Three-year history of intermittent claudication before development of first episode of coronary thrombosis, after which long-term anticoagulants continued till patient's death 15 months later. Died in his sleep at home. Coroner's post-mortem examination reported cause of death as severe coronary atherosclerosis and ruptured aortic aneurysm.

9. Man aged 51. Anticoagulant therapy continued after second episode of coronary thrombosis. Patient remained active and relatively fit for 15 months and then developed left ventricular failure. Admitted to another hospital for treatment; anticoagulant therapy continued. Died after running to his car several weeks after discharge from hospital. Coroner's post-mortem examination reported extensive fibrosis and dilatation of heart with coronary arteries narrowed to almost pinpoint diameter from advanced atherosclerosis. Thrombus present in one coronary artery. He had not been seen at our anticoagulant clinic for 10 weeks for control of his anticoagulant therapy and did not attend the New End Clinic after his discharge from hospital.

It can be seen from the above that in four of the nine patients adequate anticoagulant cover was not considered to have been given. In a fifth patient anticoagulants were stopped one week before death, but it was obvious from his critical state that death was inevitable.

Final evaluation of the results of long-term anticoagulant therapy and the decision whether or not it should be used in the treatment of all patients will depend on the results achieved when all patients have been treated for a much longer period. Nevertheless these preliminary results are promising enough to warrant wider adoption of the treatments. It should be noted, however, that several patients who have been on anticoagulant therapy for many years have died from progressive cardiac failure, so that while long-term anticoagulant therapy significantly prolongs life it is not a sufficient cure in itself.

Control of Long-term Anticoagulant Therapy

The control of long-term anticoagulant therapy demands considerable skill and individual attention for each patient. This is necessary not only to prevent haemorrhage but also—and just as important—to ensure adequate treatment. It is essential when dealing with large numbers of patients to provide special clinics. For laboratory control both Quick's and Owren's methods give reliable results, the essential factor with both methods being the provision of a reliable thromboplastin (Toohey, 1958a).

Choice of Anticoagulant Drug

Two anticoagulant drugs were used—the very long-acting "marcoumar" and the shorter-acting phenindione ("dindevan"). Once experience was gained in allowing for the very slow delayed effect and pronounced cumulative action the results with marcoumar were excellent. When the correct maintenance dose has been exactly ascertained there is much less fluctuation in the prothrombin times with long-acting drugs owing to their cumulative effect, and therefore much less danger of the patient's escaping from anticoagulant cover. This is particularly important if inadvertently the patient misses a dose.

From a brief experience with the anticoagulant warfarin sodium, which gives excellent results for short-term therapy (Toohey, 1958b), it seems that this anticoagulant will also prove valuable for long-term treatment and will give better results than phenindione.

Undoubtedly the greatest single factor in maintaining adequate long-term anticoagulant cover and also in avoiding

severe haemorrhage is experience in the regulation of the dose of the anticoagulant drug. The greater the care taken to determine the exact maintenance dose, the smaller the fluctuations in the prothrombin times and also the less frequent the need for blood tests. A very exact assessment of the maintenance dose was possible for most patients, with the result that out of a total of 117 patients under treatment 105 attend only at intervals of 6 to 12 weeks for blood tests and are nevertheless having adequate anticoagulant cover. A small number of patients are for some reason less stable, but even in this group the minimum period between blood tests is four weeks.

It is amazing how stable are the requirements of the majority of patients with regard to the dose of the anticoagulant drug, provided that there is not intercurrent illness or marked change in diet and that the patient is not taking certain drugs which may interfere with the treatment. In the absence of such circumstances, any marked fluctuation in the prothrombin times will usually be caused by too large a change in the dosage of the anticoagulant drug. It has been definitely found in this series that as much as a 5% variation in the dose will cause appreciable fluctuations in the prothrombin times over a period of a few weeks. In the vast majority of patients it is essential to assess the maintenance dose to within 2% to 3% if the prothrombin times are to remain steady over long periods and so allow the patient to attend at intervals of 8 to 12 weeks. Such widely spaced attendances are of course highly desirable.

Instructions for Patients

The patients must be given the fullest information about all aspects of their treatment, such as the dose, strength of tablet, possible side-effects, the danger of intercurrent illness, and the danger of taking certain drugs. As long-term anticoagulant therapy has to be continued indefinitely it is only by taking all possible precautions that successful therapy can be maintained. All instructions should be written. There must be the fullest co-operation with the patient's private doctor, who must in particular be made fully aware of the danger of prescribing drugs which may interfere with the treatment, such as aspirin, phenylbutazone, and oral antibiotics—especially broad-spectrum antibiotics. The possible need to reduce, but not stop, the maintenance dose of the anticoagulant drug and the necessity to take more frequent blood tests during intercurrent illness are particularly stressed.

Surgical Procedures

Many dental extractions have been performed without undue bleeding and without the need for any material alteration in the dose of the anticoagulant. Several major operations, including intestinal anastomosis and prostatectomy, have been carried out whilst the patient has continued to have adequate anticoagulant cover. It is considered most inadvisable to stop anticoagulant therapy completely in order to carry out surgical procedures; it is only necessary to ensure that the prothrombin times are at the lower therapeutic limit of approximately twice the normal control time when Quick's method is used, or 20% to 25% by Owren's technique.

Summary and Conclusions

From 1955 onwards all patients discharged from New End Hospital who had sustained a severe attack of coronary thrombosis, particularly when complicated by heart failure, or who had had more than one episode of infarction were treated with long-term anticoagulant therapy. In all, 117 patients were treated for six months or longer. In this selected group of treated patients the incidence of recurrent infarction was 66% compared with 19% for a control series of patients. The mortality rate for the treated severe cases was 1.7%, 3.0%, and 11.6% at 6, 12, and 18 months, compared with

11.3%, 18.3%, and 24.3% for the control series of 325 unselected patients discharged from New End and other hospitals in the same group between 1948 and 1955. It can be seen, therefore, that long-term anticoagulant therapy has reduced the expected mortality rate at 18 months by at least a half.

In all, 226 patients were discharged from New End Hospital following attacks of coronary thrombosis from 1955 onwards, from which date long-term anticoagulant therapy was given to all patients with severe or recurrent infarction who could co-operate or attend for treatment. The total mortality rate for all these patients—treated severe cases and untreated milder cases—was 2.6%, 6.4%, and 13.2% and 6, 12, and 18 months. There was therefore a significant lowering of the total mortality rate compared with that of the control series. In the untreated group of patients discharged from 1955 onwards several patients died whose condition would have justified treatment, but who did not receive anticoagulant therapy because they could not co-operate or attend for control of their treatment. If these patients were excluded the mortality rate would be still lower.

Several of the most severely ill patients who have been on continuous anticoagulant therapy for many years have died from progressive cardiac failure, so that while long-term anticoagulant therapy does significantly prolong life, something more is needed to halt the underlying atherosclerosis.

Long-term anticoagulant therapy is a feasible practical procedure, and the vast majority of patients can be adequately controlled with blood tests taken not more frequently than every 8 to 12 weeks. The minimum period required for attendance for routine blood tests in the small minority of patients who prove difficult to control is four to five weeks. To ensure that patients are co-operating fully over their treatment it is essential that they should attend for their blood tests whenever possible and a "postal service" is not advised as a routine.

Full written instructions about all aspects of the treatment must be given to the patient and his private doctor, particularly with regard to the risk of bleeding, the need for more frequent blood tests during intercurrent illness, and the possible necessity for a reduction in the maintenance dose of the anticoagulant drug during such illness. The anticoagulant drug must not, however, be stopped, as there is a definite danger of a recurrence of thrombosis, particularly in severe cases. The danger of taking certain drugs such as aspirin, phenylbutazone, and oral broad-spectrum antibiotics is especially stressed.

Major surgical procedures, such as intestinal operations and prostatectomy, have been performed whilst the patients continued to have adequate anticoagulant therapy, and it is inadvisable and unnecessary to stop treatment completely at such times.

When large numbers of patients are being treated with long-term anticoagulant therapy it is essential to have special clinics with personnel who are experienced in the use of anticoagulant drugs and who fully understand the necessary laboratory procedures.

Discussion

The nephrotic syndrome in children is a fluctuating condition. It is characterized by episodes of exacerbation of proteinuria and oedema. Some children remit spontaneously, losing oedema and proteinuria permanently. Others continue to pass protein, without impairment of renal function, for long periods. A small proportion die of renal and cardiac failure or other causes. Absence of proteinuria for many months does not preclude a relapse. This makes it impossible to evaluate the results of treatment over short periods.

In two of our cases moderate doses of cortisone and prednisone did not affect the proteinuria, while a course of prednisolone produced a marked reduction. As Arneil (1956) and Lennard-Jones (1957) have also shown, prednisolone is the only form of treatment that consistently reduces or abolishes proteinuria in children. Proteinuria may recur many months after successful prednisolone treatment—as occurred in two of our children; however, these children responded to a further course. It is suggested that prolonged treatment with small doses of prednisolone—for example, 5 mg. on alternate days—may prevent relapse.

Summary

Six cases of the nephrotic syndrome in children have been treated with large doses of prednisolone and followed for periods of up to 18 months. Five cases lost their proteinuria, and three of these are protein-free at 6, 15, and 18 months after treatment. Two developed proteinuria and oedema after 3 and 15 months. Both were treated again with a course of prednisolone, with disappearance of oedema and reduction in proteinuria. One further case has continued to pass a decreased amount of protein, which was further decreased after another course of prednisolone.

ADDENDUM, August, 1958.—Since October, 1957, three of ten children—D. C., S. T., and T. J.—have had no relapses. P. M. and L. L., when last seen, some months ago, were also well. K. G. has had two more relapses; each has responded to further short courses of prednisolone (0.5 g. in two weeks). Two other cases have been treated and followed up for nine and six months respectively. Each responded to the initial course, and was kept on a maintenance dose. One of these had to be readmitted six months after his initial course, but responded to a short course of prednisolone (0.5 g. in two weeks). The latter remains well, but continues to have proteinuria, despite maintenance therapy.

Our thanks are due to Dr. J. Forest Smith, Dr. H. K. Goadby, and Dr. B. D. R. Wilson for allowing us access to their cases and for their encouragement, and to Dr. W. J. Griffiths for and for their encouragement, and to Dr. W. J. Griffiths for chemical studies. We are grateful to the sisters and nursing staff of the children's wards of St. Thomas's Hospital, St. Peter's Hospital, Chertsey, and St. Andrew's Hospital, Bow, for their help.

Potter, P. A. (1904). *Pediatrics* (N.Y.), 16, 129. Quoted by G. Carpenter. *Rep. Soc. Stud. Dis. Child. Lond.*, 1907, 7, 281.

The Public Health (Preservatives, etc., in Food) Regulations, 1925-1953, permit the importation of citrus fruit in not wrappers impregnated with diphenyl to the extent of not more than 40 mg. per 100 sq. in. Exporting countries now employ other methods of preservation—for example, the impregnation of the container with diphenyl or the inclusion of impregnated pads or spacers in the container—and the regulations have been amended to permit the importation and sale of citrus fruit which contains diphenyl or ortho-phenylphenol or admixtures of the two substances within prescribed limits.

EXOPHTHALMOS IN CUSHING'S SYNDROME

BY

D. CROOKE MORGAN, M.B., B.Ch., B.Sc.

Medical Registrar

AND

A. STUART MASON, M.D., M.R.C.P.

Consultant Physician

Department of Endocrinology, New End Hospital, Hampstead, London

Cushing (1932), in his original description of the syndrome that now bears his name, recorded several instances of mild-to-moderate exophthalmos. Subsequent reports have confirmed this finding. Although there does not appear to be any example of severe exophthalmos, some degree of proptosis was found in 8% of 189 patients with Cushing's syndrome reviewed by Plotz *et al.* (1952).

The following case appears worthy of record because of the unusual course of the disease in which the appearance of malignant exophthalmos preceded the evolution of severe Cushing's syndrome.

Case History

A woman of 39 was admitted to the London Hospital on July 11, 1956. She had been agitated and depressed for the six weeks before admission, and for the previous three days had been very excitable, unable to converse intelligently, and was quoting odd phrases from the Bible.

Her ankles had been swollen four weeks before admission, the oedema being dispersed by acetazolamide. Her eyes had been slightly prominent for as long as her relatives could remember, but for the previous 18 months they had been sore and watering, although no increase in prominence had been noted.

On examination she was found to be obviously psychotic. Bilateral proptosis was present in marked degree, with severe conjunctivitis and slight ptosis on the right. Thyrotoxicosis was looked for particularly, but no sign other than her exophthalmos was found. A provisional diagnosis of an intracranial tumour was made.

During the first night in hospital she made an attempt at suicide by cutting her wrists with pieces of a broken spectacle lens. Consequently on July 13 she was transferred to Warley Hospital, where she was found to be mentally inaccessible, with delusions and hallucinations. Physical examination revealed obesity and male distribution of body hair, together with a severe proptosis. Her blood pressure was 120/90.

By July 16 her exophthalmos had increased to such an extent that orbital decompression was considered. Two days later electric convulsion therapy was started and a course of seven electroplexies completed on July 27. A considerable improvement in her mental condition had occurred and her exophthalmos had diminished.

On August 16 her mental condition relapsed, her eyes became more prominent, but a further course of seven electroplexies improved her condition. Up to this time menstruation had been normal, but she then developed amenorrhoea, which persisted until December. On September 3 her blood pressure was 180/130. Another relapse necessitated a further course of electric convulsion therapy, but by October 21 she had so improved that she could be discharged. She was then referred to one of us (A. S. M.), and on this occasion volunteered the fact that she thought her face was changing and that some fat was

collecting over her shoulder girdle. On examination her face was fat and heavy, with a faint hairy down over her chin. Her scalp hair was thin. Bilateral severe exophthalmos was present. There was no ophthalmoplegia. Her skin was rather dry, and her blood pressure was 170/125.

At that time she did not exhibit the habitus of Cushing's syndrome, and her general appearance and skin texture were suggestive of myxoedema. Thyroid extract, in a dose

FIG. 1

of 3 gr. (0.2 g.) daily, was therefore started on September 20. On the 26th her exophthalmos was thought to be rather worse, but did not progress subsequently.

However, by November 1 a rounded face, fat around the neck, and a decrease in the bulk of the limb muscles became apparent. Stilboestrol in a dose of 2 mg. daily was started. At that time the 17-ketosteroid excretion was 14.1 mg./24 hours, and the skull did not show any radiological abnormality.

On January 30, 1957, she was admitted to New End Hospital for further investigation. Gross bilateral exophthalmos was still present with chemosis and conjunctivitis, though the retro-orbital tension was not unduly raised (Figs. 1 and 2).

FIG. 2

Her blood pressure was 175/120 at rest in bed. Two months previously the diagnosis had been problematic, but the subsequent rapid change in her appearance left no doubt that the diagnosis was Cushing's syndrome.

Investigations.—Hb, 103%; total W.B.C. 14,000/c.mm.; E.S.R., 12 mm. in one hour (Westergren); total serum proteins, 5.8 g./100 ml. (albumin 3.9 g., globulin 1.9 g.); serum sodium 156 mEq/l.; potassium, 5 mEq/l.; bicarbonate, 29 mEq/l.; chlorides, 95 mEq/l.; cholesterol, 225 mg./100 ml.; 17-ketosteroids (Medical Research Council, 1951), 7.7 mg./24 hours; 17-hydroxycorticoids (Appleby *et al.*, 1955), 38.2 mg./24 hours, and by the method of Reddy (1954) 21.4 mg./24 hours. Glucose-tolerance test (50 g. of glucose given orally): fasting blood sugar, 95 mg./

100 ml.; 30 minutes, 123 mg.; 60 minutes, 180 mg.; 90 minutes, 200 mg.; 120 minutes, 205 mg.; 150 minutes, 198 mg. X-ray examination of lumbar spine showed moderate osteoporosis and multiple disk lesions.

On February 6 she began menstruating. Nine days later, crops of petechiae appeared over her right breast, right arm, and right side of her back. Her blood pressure in bed and at rest was constantly in the region of 180/130.

Further Investigations.—Hess test positive. Platelets, 204,000/c.mm.; clotting-time (Lee-White), 3½ minutes; bleeding-time, 4½ minutes; 17-ketosteroids (M.R.C., 1951), 12.9 mg./24 hours; 17-hydroxycorticoids (Appleby *et al.*, 1955), 66.1 mg./24 hours, and by the method of Reddy (1954) 34.9 mg./24 hours.

While these investigations were being completed her mental state did not give rise to anxiety, and she appeared to be a calm and composed patient. On February 16, during the early hours of the morning, she jumped from a bathroom window to the street, two stories below. She died a few minutes later.

The cause of death was found at necropsy (Dr. F. Camps) to be due to a ruptured aorta. The endocrine glands all appeared to be of normal size. Dr. A. B. Bratton gave the following histological report. "Hyaline changes in numerous basophil cells in the anterior lobe of the pituitary correspond to those described by Crooke (1935). Slight hyperplasia of the adrenal cortex is present. There are numerous corpora fibrosa and a few cystic follicles in a slightly fibrotic ovary. One small microfollicular adenoma of the thyroid, otherwise normal thyroid tissue. The myocardium of the left ventricle is hypertrophied."

Discussion

The salient point in the natural history of this patient was the rapid progression of the signs of Cushing's syndrome after a period of 30 weeks in which the picture was that of a malignant exophthalmos and an episodic mental state consisting of an agitated depression. There was no evidence of thyroid dysfunction. The exophthalmos varied *pari passu* with the psychotic episodes, but did not become pronounced again as the adrenal disorder became obvious and progressive. The tragic end to this case again emphasizes the great care needed although mental disturbance is not obvious.

The occurrence of mental changes as a part of Cushing's syndrome is well known (Schleisinger and Horwitz, 1940; Spillane, 1951; Plotz *et al.*, 1952; Trethowan and Cobb, 1952). Starr (1952), in a series of 53 cases, observed that depression was the most frequent finding. The suicide rate of the series was 1,000 times that of the general population.

The pathological physiology of exophthalmos has been discussed extensively (Greene, 1955), but as yet there is no full explanation. All the evidence points to a pituitary-thyroid relationship. Apparent exophthalmos has been produced in the experimental animal by the administration of cortisone (Aterman, 1952; Aterman and Greenberg, 1953, 1954), and it might be possible to extrapolate such work to explain the findings in our case. However, another

FIG. 3

explanation has been offered by Boas and Scow (1954) for these results. They considered that the apparent exophthalmos was due to retarded body growth induced by cortisone. Essex (1955) also held the view that body growth is retarded by cortisone, while the eye, as an ectodermal structure, was little affected. Wyn Williams (1955) found that this cortisone-induced exophthalmos could be produced only in the growing animal. Moreover, it has been suggested that systemic cortisone might improve exophthalmos, and, although this was not borne out in a trial carried out under the auspices of the Medical Research Council (1955), no case was made worse by such treatment.

Although no definite mechanism can be implicated, the natural history of this case, with exophthalmos preceding the other signs of Cushing's syndrome, would suggest that the primary disturbance was hypothalamic or pituitary rather than adrenal.

Summary

A case of Cushing's syndrome with mental disturbance and malignant exophthalmos is described. A possible mechanism of the exophthalmos is discussed. It is suggested that the primary lesion of Cushing's syndrome was in the hypothalamus or pituitary rather than the adrenal glands.

We thank Dr. A. E. Clark-Kennedy and Dr. J. R. P. Edkins for access to the case records compiled while this patient was under their care.

RENAL FAILURE DUE TO PARA-AMINOSALICYLIC ACID

BY

DIANA OWEN, M.R.C.S., L.R.C.P.

Assistant Medical Officer, Colindale Hospital, London

Drug allergy has been said to have ousted syphilis in recent years as "the great imitator." Florid cases of allergic reactions to para-aminosalicylic acid (P.A.S.) have often been reported, but associated renal involvement has been uncommon and usually confined to patients who also had hepatitis. Accounts of allergic reactions to P.A.S. with renal failure and jaundice are given by Cuthbert (1950), Livingstone and Street (1950), Jeffrey *et al.* (1952), and Mann (1953). Two papers have also described renal failure in patients having allergic reactions to P.A.S. without jaundice, but in the earlier case (Le Melletier and Gerphagnon, 1950), the patient was already almost moribund with tuberculosis. In the other paper, Silverman *et al.* (1956) report a case of "toxic nephritis" without clinical but with biochemical evidence of hepatic damage. The following account is therefore the first authentic report of a case of renal failure due to P.A.S. without hepatitis.

Case Report

An Irishman of 31 was first found to be suffering from pulmonary tuberculosis, with a positive sputum, in April, 1956. In August, he was admitted to hospital, where he was given 1 g. of streptomycin daily with calcium B-P.A.S., 3.5 g. t.i.d., and isoniazid, 100 mg. t.i.d., for 83 days.

He was transferred to Colindale Hospital on October 30. On admission he was a healthy-looking man with a symptomless goitre. There was no clinical evidence of thyrotoxicosis. His temperature was 98.4° F. (36.9° C.), pulse 84, blood pressure 130/80. No abnormal physical signs were found in the chest or any other system. X-ray examination revealed bilateral apical pulmonary tuberculosis without cavitation. Sputum was negative for acid-fast bacilli on smear and culture. The E.S.R. (Westergren) was 3 mm. in one hour. The urine was found to contain sugar. Fasting blood sugar was 110 mg./100 ml. The glucose-tolerance curve was within normal limits. The blood count was normal; Hb, 106%.

There was no family history of asthma or other allergic conditions. His mother had a goitre. The patient did not remember ever having had a drug reaction. He had never had asthma or other manifestations of allergy.

On November 3 the patient started streptomycin, 1 g. three times a week, with daily sodium P.A.S. 12 g., and isoniazid 300 mg. by mouth. He made satisfactory progress until December 8 and 9, when the evening temperature was 99° F. (37.2° C.), and on December 10 it rose to 101.6° F. (38.7° C.). An injection of penicillin was given. Next morning a pink macular rash was noticed. The posterior cervical glands were enlarged, firm, and discrete, but not painful or tender. The patient was thought to be suffering from rubella. The evening temperature on December 11 was 103° F. (39.4° C.). Although no complaint of sore throat had been made the fauces were reddened. P.A.S. and isoniazid were continued, and streptomycin, P.A.S., and isoniazid were given the next day, December 12, as usual. That evening the temperature rose to 103.2° F. (39.5° C.) with enlargement of glands in the anterior triangles of the neck. Another injection of penicillin was given.

On December 13 the possibility of drug hypersensitivity was considered, and penicillin, streptomycin, P.A.S., and isoniazid were discontinued. A course of diphenhydramine hydrochloride was started. The same evening the temperature fell to 100° F. (37.8° C.), and by the evening of the 14th it was normal and remained so for over 36 hours, but the rash had become red and blotchy with considerable pruritus, and glands could be felt in the axillae and groins. The conjunctivae were suffused. The blood count remained normal. The Wassermann reaction was negative. No glandular fever cells were seen in the blood then or at any time. The Paul-Bunnell test and all other agglutination reactions were negative.

On December 16 and 17, while he was still on diphenhydramine hydrochloride, the temperature rose again to 99° and 102.2° F. (37.2 and 39° C.) respectively, and the drug was therefore discontinued.

On December 19 there was an evening pyrexia of 105° F. (40.6° C.) with a fresh crop of glands in the post-auricular regions, and the spleen was found to be palpable. One dose of chlortetracycline was given that night, but the drug was discontinued owing to vomiting. Although the rash gradually faded without desquamation, the urine became scanty and highly coloured. It contained sugar and a trace of albumin.

Another spike of pyrexia—101.4° F. (38.6° C.)—occurred on December 23 with a transient erythematous rash on the trunk. The general condition remained good, but the patient was still vomiting, and only 2 oz. (57 ml.) of urine had been passed in the previous 24 hours. This was solid with albumin and contained leucocytes, erythrocytes, and hyaline and granular casts. Culture was sterile. The blood urea was

found to be 150 mg./100 ml. Fluids were immediately restricted by mouth and penicillin was started. No pitting oedema was observed at any time. Daily blood-pressure readings never rose above 150/90. At no time was there clinical evidence of hepatic involvement. The blood count remained normal throughout. The blood urea rose to 245 mg./100 ml. on December 27 and thereafter fell, until by January 7, 1957, it was normal. (Urea concentration test was also normal on January 7.)

By December 30 fluid balance had been re-established and the spleen was no longer palpable. (The glands subsided more gradually, the last disappearing on February 13.) Urine was clear of red cells by December 31, casts by January 11, and albumin and leucocytes by January 21. Glycosuria persisted. A 24-hour specimen of urine contained no acid-fast bacilli on Löwenstein culture. Serum protein electrophoresis still showed a slight decrease in albumin and increase in α_2 and γ globulins on January 7.

Despite courses of penicillin and chlortetracycline the temperature subsided very gradually and did not settle finally until the middle of January.

Test doses of chlortetracycline and penicillin during March gave no reaction, nor did isoniazid or streptomycin.

On March 8, 4 g. of sodium P.A.S. given orally at 10 a.m. was followed by a prickling sensation in the skin during the afternoon. The temperature at 5 p.m. was 100° F. (37.8° C.). 50 mg. of diphenhydramine was given. At 10 p.m. the temperature was 101.8° F. (38.8° C.) and the patient vomited. Diphenhydramine, 100 mg., was then given and the temperature fell to normal. There was a deficit of 40 oz. (1,140 ml.) in urinary output during the next 48 hours. Blood urea was 30 mg./100 ml. The urine contained no albumin.

The patient was discharged home well on April 4.

Discussion

By far the commonest serious complication of P.A.S. therapy is hepatitis, an excellent review of which is given by Hensler *et al.* (1957). Hepatitis usually accompanies a severe allergic reaction characterized by fever, rash with pruritus, sore throat, conjunctivitis, eosinophilia, and enlargement of glands and spleen, or most of these signs.

It was noted by Lichtenstein and Cannemeyer (1953) and Cannemeyer *et al.* (1955) that 0.3% of their patients treated with P.A.S. had reactions of some sort, but in over 3,000 cases none had renal complications. This infrequency is confirmed in the literature reviewed here. P.A.S. remains a comparatively safe drug whose usefulness outweighs the possibility of occasional severe complications.

It is noteworthy that the patient described here took calcium B-P.A.S. for 83 days without mishap. After 35 days of sodium P.A.S. his severe allergic illness developed. Unfortunately, after recovery, a test dose of calcium B-P.A.S. was not tried. All the allergic reactions already alluded to were due to sodium P.A.S. (Cuthbert, 1950; Livingstone and Street, 1950; Jeffery *et al.*, 1952), or P.A.S. itself (Le Melletier, 1950; Mann, 1953; Silverman *et al.*, 1956). Phillips *et al.* (1957) has described three cases in which the patients exhibited allergic reactions to sodium P.A.S. and

were subsequently able to take calcium B-P.A.S. uneventfully. As calcium B-P.A.S. is of comparatively recent introduction, it remains to be seen whether it does in fact reduce the incidence of allergic reactions. Pharmacologically there would appear to be no reason to expect this.

Summary

A review of the literature of renal complications of P.A.S. therapy is given. The frequency of association of renal with hepatic complications is discussed.

A case is described of severe renal failure due to sodium P.A.S. as part of an allergic reaction to the drug. The diagnosis was confirmed by subsequent test doses. The patient made a spontaneous recovery some time after the drug was stopped.

The rarity of renal complications of P.A.S. therapy is mentioned. There would appear to be no indications for using P.A.S. less frequently than is at present the custom.

The possible relationship of P.A.S., sodium P.A.S., and calcium B-P.A.S. to allergic reactions is briefly considered. It is possible that calcium B-P.A.S. is the safest of the group available for routine use at the present time.

I am grateful to Dr. G. Jennings for encouragement to report this case, Dr. J. Wallace Craig for reading the manuscript, Dr. W. E. Snell for permission to publish, and Dr. Esme Davies for the pathological reports.

LEIOMYOMA OF OESOPHAGUS

REPORT ON TWO CASES SURGICALLY TREATED

BY

J. S. GLENNIE, F.R.C.S.Ed.

AND

K. MOGHISLI, M.D.

Thoracic Surgical Unit, Blackpool Victoria Hospital

Leiomyoma is the most common benign tumour of the oesophagus. Until recent years most cases were discovered at necropsy. Lewis and Maxfield (1954) reported 47 surgically treated and 108 post-mortem cases in their collection of 150 cases from the world literature. Whether priority of surgical treatment belongs to Sauerbruch or Ohsawa, it is clear that there has since been a new chapter in the field of practical treatment and consequently an increase in the number of surgical cases. Storey and Adams (1956) collected 110 cases of these tumours surgically treated: 16 before 1948 and 94 from 1948 to 1956.

We do not propose to review the whole literature, as this has already been done recently by several authors. However, the infrequency and the successful operative treatment of leiomyoma of the oesophagus gives us reason to present our two personal cases.

Case 1

A male nurse aged 43 was referred to the E.N.T. out-patient department on June 15, 1956, complaining of dysphagia and retrosternal discomfort when swallowing. He stated that six weeks previously he had an attack of influenza, following which the dysphagia developed. On E.N.T. examination no abnormality was revealed. The chest x-ray examination showed no abnormality, but a barium swallow on June 26 revealed a large well-defined indentation of the middle third of the oesophagus; this was interpreted as probably due to extrinsic pressure; no hold-up of the barium occurred. On August 30 oesophagoscopy revealed only a slight swelling on the posterior wall of the oesophagus at the level of the upper and middle thirds.

FIG. 1.—Case 1. Barium swallow. Note the typical filling defect and the ring or crescent shape of the barium column.

Bronchoscopic examination was negative. A repeat barium-swallow examination again showed the filling defect at the junction of the upper and middle thirds (Fig. 1). The patient was admitted to our thoracic surgical unit on October 22, and in addition to the dysphagia some vomiting occurred and he had also lost a little weight. He had been suspected, about a year previous to the dysphagia, of having a duodenal ulcer. Otherwise he had always been in good health.

On examination he was of normal build; there were no signs of anaemia and no adenopathy. The cardiovascular and respiratory systems showed no abnormality, neither did his digestive system, apart from the dysphagia and vomiting. The abdomen was normal. Blood examination showed no anaemia, and the white-cell count was normal. The ensemble of the history and examination led us to the diagnosis of non-malignant tumour of the oesophagus, probably a leiomyoma.

Operation

On November 7 the oesophagus was explored through a right thoracotomy with the patient in the lateral position. There was no abnormality of the lung or mediastinum, but bulging and swelling of the oesophagus were found just below the arch of the azygos vein. The tumour was 3 to 4 cm. long and quite localized. A vertical incision over the wall of the oesophagus at the level of the tumour was made. The tumour, which was lying between the mucosa and the muscular layers of the wall of the oesophagus, was shelled out readily. The muscle layers of the oesophagus were repaired with fine silk. After drainage of the pleural cavity the thoracotomy wound was repaired.

Histological examination revealed a fibroleiomyoma. There was no sign of malignancy.

The immediate post-operative recovery was uneventful, and after 48 hours the patient started to drink water and then soft drinks, and later took a soft diet. After a further two weeks he was discharged, taking a normal diet, and had no dysphagia or digestive disturbance. Before discharge a barium-swallow examination showed normal passage of the barium and no filling defect. Six weeks after discharge he was very well and in a satisfactory condition. When seen on May 7, 1957, he had no dysphagia, was putting on weight, and his condition was very satisfactory.

Case 2

A schoolmaster aged 34 was first seen in November, 1956. He gave a history of two years' discomfort in the epigastric region, and dysphagia. When this dysphagia first started in 1954 he had a barium-meal examination, which was reported as normal. On questioning, he did not think he had lost any weight.

On examination there was no adenopathy. The cardiovascular and respiratory systems were normal. The abdomen was soft without any tenderness. There was no hepatosplenomegaly or anything relevant in the past history. The barium-swallow examination showed a

FIG. 2.—Case 2. The barium swallow; showing also the soft-tissue mass at the level of the filling defect of the oesophagus.

rounded filling defect in the upper oesophagus at the level of the sterno-clavicular junction. The defect in the oesophagus was smooth and suggestive of extrinsic tumour. Plain chest x-ray films from the lateral view showed a soft-tissue mass in the superior mediastinum (Fig. 2).

Oesophagoscopy at the end of December showed no abnormality. There was the impression of a hard mass pressing into the posterior wall of the oesophagus.

The patient was referred to our thoracic surgical unit with a diagnosis of chondroma or dermoid tumour pressing on the oesophagus.

On admission he gave the same history of dysphagia, and on clinical examination again no abnormality was discovered. The blood count was normal. A barium-swallow examination showed the same filling defect (Fig. 3). From the long-standing dysphagia, the clinical examination, and the typical barium-swallow examination, leiomyoma of the oesophagus was diagnosed.

FIG. 3.—Barium swallow of Case 2. Again the crescent-shaped barium column with a typical filling defect is present.

Operation

The tumour appeared to be at the level of the junction of the upper and middle thirds of the oesophagus. The oesophagus was explored through a right thoracotomy, with the patient in the lateral position. No abnormality of the lung or mediastinum was found, but a fairly large tumour the size of a small orange lay in the wall of the oesophagus at the junction of the upper and middle thirds; the arch of the azygos vein was running over the middle of the tumour. The oesophagus was mobilized after ligation and division of the azygos vein; then a vertical incision was made over the tumour (about 4 cm. long). The incision was through the muscle layers only, and the tumour was shelled out fairly easily. The tumour was lobulated (Fig. 4), the

FIG. 4.—Case 2. Lobulated growth.

mucosa remaining intact. The muscle layers of the oesophagus were then stitched with fine silk, and after insertion of a drainage tube into the right pleural cavity the thoracotomy wound was repaired.

The immediate post-operative recovery was uneventful, and after 48 hours the patient was given water and then soft drinks. A week later he was eating very well on a soft diet. After two weeks he was discharged from hospital. His general condition was then very satisfactory and he had no digestive discomfort or dysphagia.

When seen six weeks after operation he was very well. A barium-swallow examination at that time showed that the barium passed quite normally through the oesophagus, the contours of which appeared to be normal. He later lived abroad, and has written to tell us that he has had no dysphagia and was enjoying his food.

Discussion

Authors who have collected cases of leiomyoma of the oesophagus from the world literature record that most leiomyomas usually occur in the lower and middle thirds of this organ. In our cases they were found at the junction of the upper and middle thirds. The age range of patients is between the third and sixth decades of life. In all series there are more males than females, the ratio being as high as 2 to 1.

Symptoms

1. *Dysphagia*.—Both of our patients complained of dysphagia. Many cases may be asymptomatic—about 50% in the series of Johnston *et al.* (1953). Obviously the presence of symptoms depends upon the size and location of the tumour, as it is of mechanical origin. Dysphagia is the most common symptom, alone or associated with other symptoms. The myoma being a slowly growing tumour, dysphagia may be present for a long time with various degrees of severity. In Case 2 the patient had dysphagia for three years before his operation. Dysphagia may be intermittent, as in our patients, and in the case of Chalmot *et al.* (1951). Most if not all of the oesophageal conditions at one stage or another present the symptom of dysphagia, and even long-standing dysphagia is not very helpful in making the differential diagnosis; this is based on other symptoms and investigations.

2. *Loss of weight* is a relatively unimportant symptom. In spite of long-standing dysphagia in this condition, loss of weight is either absent or very slight. Only one of our patients (Case 1) lost a little weight. The other, in spite of his long-term dysphagia, had not lost weight.

3. *Other Symptoms*.—One of our patients had attacks of vomiting. Epigastric pain and discomfort are often recorded in different series, and even the respiratory disturbances can occur (for example, the patient of Chalmot *et al.* with "respiration bouché").

Physical Examination and Clinical Investigations

Physical examination is usually negative. The blood count and laboratory findings are also usually normal.

Oesophagoscopy usually reveals no lesion of the mucosa. In both of our cases this examination showed no lesion of the mucosa, but the impression of extrinsic pressure. Occasionally ulceration or congestion of the mucosal membrane can be seen (Lortat-Jacob, 1949), and then the biopsy may establish the diagnosis. The value of the oesophagoscopy is to rule out the possibility of carcinoma.

The straight x-ray film of the chest may sometimes show the presence of the mediastinal mass with or without displacement of the trachea. This was the case in one of our patients. The barium-swallow examination, on the other hand, gives the most valuable diagnostic information. Radiological features of benign tumours of the oesophagus and their differential diagnosis from malignant ones have been described by many authors, and Buckstein (1953) discusses the matter fully in his book. Benign intramural tumours of the oesophagus have many common features whatever their histological structures may be. Also, the intramural, submucosal, and extrinsic ones may be differentiated one from another, although at times with difficulty (Schatzki and Hawes, 1942).

The filling defect caused by the tumour mass has a smooth surface, and there is a ring or an arc shadow of the barium column. This filling defect has been referred to by many as the "half-moon" or "lacunar" and "crescent shape." The tumour of the lower end may produce considerable dilatation.

Treatment

Removal of the tumour by surgery is the only method of cure. The enucleation must be considered in every case from the first instant, as most of the leiomyomas can be removed in this way. The operative mortality rate has been recorded to be about 9% on the whole. The rate is lower for enucleation and higher for excision by resection

(Lewis and Maxfield, 1954). Pleural and pulmonary complications have been noted to follow enucleation; also hiatus hernia and oesophagitis when resection has been performed.

Summary and Conclusion

Leiomyomas of the oesophagus were once incidental post-mortem findings, but recently they have usually been diagnosed and removed surgically. In cases of long-standing dysphagia, without loss of weight in young and middle-aged patients, this tumour has to be considered. Investigations, particularly barium-swallow examination, lead to the diagnosis. The diagnosis of the tumour is important because most, if not all, leiomyomas of the oesophagus can be cured by enucleation.

We have presented two cases, pre-operatively diagnosed and surgically treated by enucleation.

We thank Dr. A. Rickards, of the Royal Lancaster Infirmary, for the photographs.

METASTATIC CARCINOMA OF THE PROSTATE AND BLEEDING

BY

IAN A. KELLOCK, M.D., M.R.C.P.
Senior Medical Registrar, Manchester Royal Infirmary and
Withington Hospital

AND

NIALL GALLAGHER, M.B., B.Ch., B.A.O.
Senior House Officer in Pathology, Withington Hospital,
Manchester

The phenomenon of fibrinolysis and the presence of hypofibrinogenemia in metastatic carcinoma of the prostate, if searched for, is not infrequent; for example, Tagnon, Whitmore, Schulman, and Kravitz (1953) found six cases showing fibrinolysis in their series of 48. The knowledge of the mechanism of fibrinolysis is still limited, but has been diagrammatically represented by Stefanini (1953). Tagnon *et al.* (1946) state that fibrinolysis is present when the clot of whole blood or diluted plasma disappears completely in less than 24 hours at 37° C. Furthermore, Tagnon *et al.* (1952) believe that the mechanism of fibrinolysis in the prostatic cancer may be different—that is, that the prostatic cancer itself may be the source of the enzyme responsible for the dissolution of the blood clot. Huggins and Vail (1943) demonstrated such a fibrinolytic enzyme in prostatic tissue. Ratnoff (1952) demonstrated fibrinolysis and hypofibrinogenemia in cancer process was due to release of pancreatic trypsin. McKay *et al.* (1953) described a case of mucinous carcinoma of the body of the pancreas with hypofibrinogenemia and multiple fibrin thromboses, but did not carry out tests for fibrinolysis.

The relationship between metastatic carcinoma of the prostate and bleeding is of interest in that the bleeding, which may be dangerous (Swan *et al.*, 1957), may be due to fibrinolysis and fibrinogenolysis, or to the more frequent finding of thrombocytopenia secondary to bone-marrow involvement. Clinically, the bleeding sites, which are particularly from the nose and urinary and gastro-intestinal tracts, as well as in the skin or after minor trauma, may be identical. Tagnon, Whitmore, Schulman, and Kravitz (1953) report that the platelet count may be depressed in metastatic carcinoma of the prostate with fibrinolysis, but haemorrhagic manifestations in association with fibrinolysis occur despite the presence of a normal level of platelets.

The following report concerns a case of metastatic carcinoma of the prostate with fibrinolysis, hypofibrinogenemia, hypoprothrombinemia, and thrombocytopenia, and the response to stilboestrol therapy; and it is contrasted with another case with thrombocytopenia and bleeding secondary to bone-marrow involvement.

Case 1

A man aged 68 was admitted to hospital on May 10, 1957, complaining of anorexia, loss of weight, and low back pain; immediately before admission he had a brisk rectal haemorrhage, passing about 1½ pints (850 ml.) of bright red blood.

On examination he was pale and ill, with many ecchymoses and purpuric spots over the limbs and trunk. It was noted later that there was moderately severe oozing from venepuncture sites. Rectal examination revealed a hard, irregular prostate and the presence of bright red blood. He had several moderately severe rectal haemorrhages during the first few days after admission and he had to be transfused with four pints (2.3 litres) of whole blood. The blood sent for cross-matching remained in a fluid state, any clot that had originally been present having disappeared on reaching the laboratory.

Investigations.—Radiography showed osteoplastic deposits involving the right innominate bone and lumbar vertebrae. Haemoglobin, 5.1 g./100 ml. (35% Haldane). White blood count, 6,000/c.mm. (polymorphs 65%, lymphocytes 24%, monocytes 1%, eosinophils 1%, myelocytes 2%, metamyelocytes 7%). The blood film showed some macrocytes, occasional megaloblasts, and 24 nucleated red blood cells per 100 leucocytes. Serum alkaline phosphatase, 40 K.-A. units. Total serum acid phosphatase, 6.3 K.-A. units. Alcohol stable fraction, 3.5 units. Serum bilirubin, 0.6 unit. Thymol turbidity, 0.8 unit. Platelet count (Lempert), 40,000/c.mm. Prothrombin activity (Quick's one-stage), 40% of normal control. Plasma fibrinogen level, 100 mg./100 ml. Whole-blood clotting-time (Lee and White), 6 minutes. Plasma recalcification time, 2 minutes. Capillary whole-blood clotting-time, 4 minutes. Factor 5, no deficiency. Factor 7, no deficiency. Clot retraction test (Biggs and Macfarlane, 1953): the clot was formed in normal time but was gradually lysed, thus rendering the test impossible to carry out.

Test for Fibrinolysis.—A standard fibrin clot was formed from equal quantities of normal plasma, brain thromboplastin, and M/40 calcium chloride at 37° C. The standard clot was washed free from thrombin with physiological saline and was suspended in the patient's plasma and placed in a water bath at 37° C. At the same time controls were set up, using a similar fibrin clot and normal plasma. The fibrin clot suspended in the patient's plasma was completely lysed and disappeared after four hours. Those in the control tubes were intact up to at least 48 hours.

Two-stage prothrombin time (Biggs and Douglas, 1953): true prothrombin was 70% of normal control. Sternal marrow examination: mainly normoblastic but late megakaryoblasts were seen; no neoplastic cells seen. Fractional test meal with histamine showed the presence of free acid. A

biopsy of the prostate gland showed the histological appearance of an adenocarcinoma. Repeat sternal marrow examination showed no megaloblasts but several groups of neoplastic cells.

Course and Treatment.—The initial response to vitamin B₁₂ was satisfactory, the reticulocytes rising from 3% to 13%, and the haemoglobin from 5.1 g. (35%) to 9.1 g. (61%). Megaloblasts were not seen in the peripheral blood again.

Stilboestrol, 10 mg. t.d.s., was started on May 28, and the dose was increased to 15 mg. t.d.s. on June 25. The marked improvement of fibrinogen levels and the disappearance of fibrinolysis on therapy can be seen from the Graph. There are also some improvement in prothrombin time and a rise in platelets.

The patient was discharged from hospital on August 1 on stilboestrol, 15 mg. t.d.s. His haemoglobin had risen to 12.9 g. (87%) and the clot retraction was found to be within normal limits, a firm clot being formed which did not lyse. He attends the out-patient department and has remained well, free from symptoms; there has been no recurrence of the haemorrhagic diathesis.

Graph of Case 1. ■ = Complete lysis of the suspended standard fibrin clot in four hours. □ = Complete lysis of the suspended standard fibrin clot in 12 hours. □ = No fibrinolysis up to 24-48 hours.

Case 2

A man aged 66 presented with low back pain, anorexia, loss of weight, pallor, and multiple spontaneous ecchymoses and purpura. During his stay in hospital he had a melaena.

Investigations.—Haemoglobin, 10.5 g./100 ml. (71% Haldane). White blood count, 10,500/c.mm., with 10% immature granulocytes in the differential count. In addition the blood film showed 15 nucleated red cells per 100 leucocytes. Platelet count (Lempert)—the highest figure recorded was 22,000/c.mm. Plasma recalcification time, 2½ minutes. Prothrombin time (Quick's one-stage), 18 seconds (control 12.5 seconds). Total serum acid phosphatase, 6 K.-A. units. Fibrinolysis was absent. Unfortunately, fibrinogen estimations were not carried out. Radiographs of the thoracolumbar spine showed areas in the bodies of the eleventh thoracic and second lumbar vertebrae compatible with secondary deposits.

Course.—The patient rapidly deteriorated and his haemoglobin fell to 5.7 g./100 ml. (38% Haldane). Altogether he received 6 pints (3.4 litres) of whole blood, but terminally he developed signs of a cerebral haemorrhage and died in coma nine days after admission.

Post-mortem Findings.—Carcinoma of the prostate was found with metastases in the iliac and para-aortic lymph nodes, lumbar vertebrae, and sternum. The brain showed multiple recent haemorrhages, the largest being in the right occipital lobe. Histological examination of the bone marrow showed many groups of undifferentiated neoplastic cells. Megakaryocytes were very scanty.

Discussion

Fibrinolysis was present in Case 1 but absent in Case 2. In both cases the platelets were considerably reduced, more so in Case 2. In Case 1 the platelet count has somewhat improved on therapy (see Graph).

Tagnon, Whitmore, Schulman, and Kravitz (1953) have shown in cases of metastatic carcinoma of the prostate with fibrinolysis that the platelets may be normal or reduced. If the platelets are within normal limits the cause of the bleeding is due to the fibrinolysis, with or without hypofibrinogenaemia, and this alters the blood coagulation factors in such a way that the prothrombin time becomes prolonged. There is some difficulty when the platelets are reduced. The bleeding tendency due to a "leuco-erythroblastic" or myelophthisic type of anaemia with severe thrombocytopenia is illustrated by Case 2. In Case 1 the haemorrhagic manifestations were almost certainly due to the fibrinolytic mechanism. In this particular case the thrombocytopenia was probably due to the associated

"leuco-erythroblastic" anaemia. However, Tagnon, Whitmore, Schulman, and Kravitz (1953) and Swan *et al.* (1957) have reported cases of metastatic carcinoma of the prostate with fibrinolysis and thrombocytopenia, where the explanation of the latter is not clear. The clinical presentation of these two cases was very similar, and if operative procedures are contemplated this differentiation is important.

In Case 1 oestrogen therapy alone quickly abolished the patient's symptoms and the haemorrhagic diathesis, during which time a transurethral biopsy prostatectomy was performed with minimal bleeding. The resulting disappearance of fibrinolysis, improvement of the fibrinogen levels, and to a less extent the prothrombin activity can be seen from the Graph. There was no need to give corticotrophin or human fibrinogen in this case. Corticotrophin has been claimed to diminish the lysis, and the response was more rapid than with oestrogens (Stefanini *et al.*, 1953), but, if used, it should be given in conjunction with oestrogens. Tagnon, Schulman, Whitmore, and Leone (1953), however, showed that the addition of testosterone to a maintenance dose of oestrogens caused an increase in the patient's symptoms and serum acid phosphatase level, as well as the reappearance of fibrinolysis. Orchidectomy does not seem to be justifiable in Case 1 at the present time. However, if fibrinolysis and hypofibrinogenaemia should return, then bilateral orchidectomy, with probably the addition of human fibrinogen, may be required. Swan *et al.* (1957) have recommended fractionated fibrinogen or triple-strength reconstituted dried plasma as the only type of emergency therapy. This has not been necessary in Case 1.

Tagnon, Whitmore, *et al.* (1952), and Tagnon, Whitmore, Schulman, and Kravitz (1953) found no constant correlation between the occurrence of fibrinolysis and the level of acid phosphatase in the serum. There appears to be no satisfactory explanation for this. They also state that the test for the level of acid phosphatase in the serum cannot be replaced by that of fibrinolysis, since the latter occurs in only approximately 12% of patients with metastatic carcinoma of the prostate. In Case 1 the correlation between the serum acid phosphatase levels and the occurrence of fibrinolysis is variable (see Graph). This lack of correlation has still to be fully explained.

Summary

A case of metastatic carcinoma of the prostate with a haemorrhagic diathesis secondary to a circulating fibrinolysin (Case 1) is reported, and is contrasted with Case 2, with thrombocytopenia and bleeding secondary to bone-marrow involvement.

Therapy with stilboestrol alone caused the fibrinolysis to disappear in Case 1, with subsequent improvement of the fibrinogen level and prothrombin time. A transurethral biopsy prostatectomy was carried out during oestrogen control.

No correlation was found in Case 1 between the occurrence of fibrinolysis and the level of acid phosphatase in the serum.

We thank Mr. H. T. Cox for permission to publish Case 1, and Mr. William Lawson, F.I.M.L.T., for his help and technical assistance.

ACUTE RADIATION NEPHRITIS IN CHILDHOOD

BY

J. SWANSON BECK, M.B., B.Sc., F.R.F.P.S.

Pathological Registrar, University and Western Infirmary, Glasgow

The following case of acute radiation nephritis associated with a uraemic haemolytic anaemia is reported because of the interest aroused by the annotation in the *British Medical Journal* of May 3, 1958 (p. 1053), on the effect of x-irradiation on the kidney.

Case Report

The patient, a pale normally developed girl of 2½ years, was first seen in January, 1957, when a large firm mass was found filling the whole of the left side of the abdomen. This was removed surgically and found to be a Wilms's tumour. She made an uneventful post-operative recovery, and a four-weeks course of radiotherapy (3,250 r) was given

FIG. 1.—Blood film showing "burr" cells, anisocytosis, and polychromasia. (×500.)

to the left renal area. She remained well until October, when a metastasis was discovered in the right perirenal fat. This could be treated only by a second course of radiotherapy (3,000 r) to the right renal area over a period of three weeks, after which the abdominal mass could no longer be palpated. On January 17, 1958, it was noted that the child, although still pale, was gaining weight, but when seen on February 7 she showed marked pallor, ankle and face oedema, full and bounding pulse, and enlargement of the heart in the transverse diameter. The B.P. was 130/85 mm. Hg. The urine showed albumin ++, R.B.C. ++, pus cells +, and a moderate number of granular and hyaline casts. The blood urea was 140 mg./100 ml. and the haemoglobin 6.2 g./100 ml. Blood films showed marked anisocytosis, polychromasia, and poikilocytosis with numerous "burr" cells of the type usually associated with the haemolytic anaemia of uraemia in childhood (Fig. 1). The white-cell count was 19,000, with a normal differential.

The child's condition deteriorated rapidly, and the blood pressure fluctuated between 135/80 and 170/110 mm. Hg. The blood urea rose progressively to 320 mg./100 ml., and she died on February 13, six days after the onset of the symptoms of acute nephritis.

Post-mortem Findings

The body was that of a pale, ill-nourished female child showing severe anasarca and extensive purpura. The heart (160 g.) showed marked left ventricular hypertrophy and

electrophoresis of serum in the younger brother was carried out, and the result showed him to be lacking completely in gamma-globulin. It would seem reasonable, therefore, to presume that Case 1 likewise lacked gamma-globulin, and was probably an example of congenital agammaglobulinaemia. The other cases here reported were probably examples of "physiological transient hypogammaglobulinaemia of infancy" (Janeway and Gitlin, 1957). These workers quote Orlandini's figures for normal gamma-globulin levels in the first two years of life and suggest that the initial fall and subsequent rise to normal represents a physiological state rather than a disease.

Janeway and Gitlin also comment on the possible relationship between agammaglobulinaemia and progressive vaccinia. They think it possible that there are gradations of agammaglobulinaemia and that infants with complete agammaglobulinaemia, or even transient hypogammaglobulinaemia, who are vaccinated in early infancy may be overwhelmed because other mechanisms of resistance are less well developed. In their paper they quote L. Pillemer as stating that normal levels of serum complement and properdin are found in congenital agammaglobulinaemia.

The mothers of three of the infants (including the one who died) had been vaccinated in infancy or early childhood, and so presumably had very little antibody to pass on to their infants. Janeway and Gitlin (1957) stated that it is not so much the quantity of gamma-globulin that the infant receives from its mother as the quality—that is, its content of specific antibodies.

All our patients were male, and it is interesting to note that all cases of agammaglobulinaemia have been male except for Keidan's case.

The method of vaccination in three of the infants was by a 1-in. (6-mm.) linear scratch, and the other by two 1-in. (6-mm.) scratches at right angles to each other. Two had been vaccinated at a clinic and two by their family doctor. The lymph for three was from the same supplier but of different batch numbers, while the fourth was done by lymph from a different supplier. Several other infants had been vaccinated by these methods, the same batches of lymph being used without ill effects.

Summary and Conclusions

Four cases of generalized vaccinia are reported, with one death. The role of agammaglobulinaemia and antibody formation is discussed. The treatment with hyperimmune vaccinia gamma-globulin is described.

It is felt that generalized vaccinia occurs in some infants because of a failure of their resistance mechanism. Whether or not the failure to form gamma-globulin and/or antibodies is the essential defect, it would appear necessary that infants developing any of the serious cutaneous complications of smallpox vaccination should be treated as soon as possible with hyperimmune vaccinia gamma-globulin and a wide-spectrum antibiotic.

We thank Professor John Craig for his advice in compiling this paper, Dr. T. E. Anderson and Dr. Alan Lyell for permission to publish Cases 3 and 4, and Dr. H. Thom for carrying out the electrophoretic studies.

Medical Memoranda

Case of Progressive Vaccinia

A case of progressive vaccinia which responded well to hyperimmune vaccinia gamma-globulin is described below.

CASE REPORT

A West African infant aged 10 months was admitted to the South Western Hospital on March 25 with a generalized vaccinia eruption. He was first seen by his doctor on the previous day, when the lesions were reported to be pustular. The infant had been in hospital on two occasions with dietetic troubles, and on the second occasion was treated for ichthyosis. Primary vaccination was performed at a clinic on March 15. His mother stated that the rash appeared all over the body on March 22 and she noticed a swelling "under the left arm."

On admission his temperature was 102.8° F. (39.3° C.), pulse 150, and respirations 50. Apart from the skin, physical examination revealed nothing abnormal. The lungs were clear.

There was a raw granulating area 1 by 1 in. (2.5 by 1.25 cm.) over the left deltoid, presumably the site of vaccination. Extending both upwards and downwards from this point on the outer surface was a profuse crop of umbilicated vesicles, circular in shape and quite superficial. Small crops of lesions were scattered over the rest of the body, including the face and scalp, in situations which the child could reach, and very possibly due to auto-inoculation. There were only two or three vesicles on the back. The colour of the lesions was difficult to gauge owing to the deep pigmentation. The axillary glands were enlarged, especially on the left side. Fresh lesions appeared daily up to March 28, especially on the face; the conjunctivae and oropharynx remained clear; and the granulating area round the site of vaccination extended to the shoulder and elbow on the external surface. The temperature remained raised, varying between 101 and 103° F. (38.3 and 39.4° C.), the appetite was poor and the infant obviously toxic.

On March 29 blood was withdrawn for antibody estimation and 1 g. of hyperimmune vaccinia gamma-globulin was given intramuscularly. This dose was repeated 24 hours later. The effect was dramatic: no fresh lesions appeared; scabs formed and separated quickly, leaving shallow foveate scars. 27 hours after the first injection the temperature fell to 98.8° F. (37.1° C.), and thereafter fluctuated between 98 and 99° F. (36.7 and 37.2° C.) until April 1, when it remained normal until discharge. The child's general condition improved rapidly and the appetite returned. By April 10 all scabs were separated and the granulating area was soundly healed. There was still some irritation, and gloves were necessary.

From admission until March 20 he was given 250,000 units of penicillin, six-hourly, without effect. This was supplemented on March 27 with sulphonamides with similar lack of response.

Dr. F. O. MacCallum, of the Virus Reference Laboratory, reported that the serum contained 640 mg. of gamma-globulin per 100 ml., which he stated was a normal level. A heavy growth of vaccinia virus was obtained from the scabs. The child was discharged on April 10.

COMMENT

The normal level of gamma-globulin, in spite of the fact that lesions were continuing to appear and the general condition of the child to deteriorate, followed by rapid response to hyperimmune gamma-globulin, suggests that this is an instance of dysgammaglobulinaemia as described

AUG. 23, 1958

by Kempe *et al.* (1956) and Lewis and Johnson (1957), the deficiency being one of quality rather than quantity.

I thank Dr. J. Pickford Marsden for his advice in the case, and Dr. F. O. MacCallum for carrying out the virus investigations.

J. C. BLAKE, M.B., D.P.H.,
Physician-in-charge, Infectious Diseases Unit,
South Western Hospital.

Susceptibility to Methylpentynol and Methylpentynol Carbamate

Methylpentynol carbamate ("oblivon carbamate") has been used as an alternative to methylpentynol. Non-specific adverse effects have been recorded after a few daily specific adverse effects have been recorded after a few daily oral doses of 1-2 g. of methylpentynol (May and Ebaugh, 1953; Marley and Chambers, 1956) and after larger (1-3 g.) and more protracted dosage (one to seven weeks) with methylpentynol carbamate (Bartholomew *et al.*, 1958). These last workers stressed that toxic abnormalities were unlikely if the daily oral dose of the carbamate did not exceed 1 g. It seemed important to ascertain whether this stricture held good for a population known to be especially sensitive to methylpentynol.

METHODS

Methylpentynol carbamate was administered to 10 subjects who had previously developed toxic phenomena while receiving a five-day therapeutic trial of 0.5 g. q.d.s. of methylpentynol, a baseline of individual reaction having been obtained by the immediate prior administration of inert capsules for five days. Similarly with the carbamate, inert tablets were prescribed for five days and were immediately succeeded by 0.2 g. q.d.s. of the active substance for the same period. A lapse of at least a month occurred between the two drug trials, and the patient received no other medication during either the placebo or the drug phase.

Their consent having been obtained, the subjects were informed that they would receive a drug from which they might or might not derive benefit. Each was interviewed daily, and if marked toxic features appeared the drug was withdrawn.

Toxic developments were graded into three categories. A maximal toxic reaction presented with pupillary abnormalities, nystagmus, diplopia, ptosis, dysarthria, and tremor of the outstretched tongue. A cerebellar type of ataxia of the outstretched tongue. A cerebellar type of ataxia of the limbs or admixtures of this with a posterior-column type of ataxia and a positive Romberg sign. A minimal toxic reaction was epitomized by little more than nystagmus on conjugate lateral gaze and perhaps slight unsteadiness of gait or drowsiness. No reaction to the drug implied the absence of physical signs, although there might be a concomitant change of mood such as mild elation. The data obtained were analysed by means of an arc-sine transformation, a useful test of significance for small populations (Davies, 1954).

The series included five males and five females with an age range from 19 to 45 years, and minimal and maximal weights of 8 st. 6 lb. and 11 st. 13 lb. (53.52 and 75.75 kg.).

RESULTS

The distribution of patients allotted to the three clinical gradings for both drugs is depicted in the Table. This shows that there is a much smaller occurrence of toxic effects with methylpentynol carbamate than with methylpentynol. On analysis with the arc-sine transformation, the proportion of patients developing adverse features with methylpentynol (10/10) is found to be significantly greater

Distribution for Clinical Response to Methylpentynol and Methylpentynol Carbamate

Drug	Clinical Grading*		
	1	2	3
Methylpentynol	0	3	7
Methylpentynol carbamate	6	3	1

* Clinical grading: 3 = maximal toxic response; 2 = minimal toxic response; 1 = no toxic response.

than the proportion manifesting susceptibility to methylpentynol carbamate (4/10), the critical ratio being 3.96 ($P < 0.001$).

The time at which toxic phenomena with the two substances was first exhibited, and the number of subjects, are shown in the Chart; from this it can be seen that the maximum incidence was at the third day, although no instance occurred prior to this.

The details relating to the only subject showing a maximal toxic response to methylpentynol carbamate are as follows:

The patient was an unmarried woman weighing 9 st. 4 lb. (46.72 kg.) and aged 45. After five days of methylpentynol carbamate (0.2 g. q.d.s.), she had suffusion of the conjunctivae, sustained rhythmic nystagmus on conjugate lateral

Time and incidence of first appearance of toxic signs with methylpentynol and methylpentynol carbamate.

gaze, bilateral ptosis, sluggish reaction of the pupils to light, loss of tone in the facial musculature, dysarthria, and tremor of the outstretched tongue. There were cerebellar defects, including dysidiadokokinesis and ataxia on the finger-nose test in the upper limbs, with ataxia on the heel-shin test in the lower limbs. Her gait was ataxic, associated with a positive Romberg sign and overall reduction of the tendon reflexes. Her mental state was one of mild depression with impairment of attention and concentration, although orientation was correct. Within three days of stopping the drug the clinical abnormalities disappeared.

COMMENT

It is shown that, for the five-day period under scrutiny, methylpentynol carbamate is much superior to methylpentynol in its freedom from incidental toxicity. However, in a population known to be especially sensitive to methylpentynol, the use of the carbamate as an alternative in doses of 1 g. a day, or greater, is likely to be followed by the early manifestation of toxic signs.

I thank Dr. Dennis Leigh for permission to publish these findings, and British Schering Ltd. for a generous supply of methylpentynol and its carbamate.

Reviews

RECENT ADVANCES IN UROLOGY

Recent Advances in Urology. By Howard G. Hanley, M.D., F.R.C.S., with the assistance of specialist contributors. (Pp. 270+viii; illustrated. 30s.) London: J. and A. Churchill Ltd. 1957.

The value of the Recent Advances Series lies in the fact that each volume records the most important works which have been published in the past few years in one particular specialty and indicates which of the theories and techniques are most widely accepted. The opening chapter of this one deals with how the modern conception of renal function, body-fluid disturbances, and blood electrolytes may be correlated with the causation and treatment of renal failure. The value of the numerous new methods of x-ray diagnosis of urological diseases is discussed and the techniques are described. The large number of modifications in operations on the renal pelvis which have been devised to relieve hydronephrosis indicates the modern tendency to conserve renal tissue whenever possible, which has culminated in the popularity of partial nephrectomy. The ever-controversial topic of the treatment of prostatic obstruction in acute and chronic retention is reviewed in the light of new methods of bladder drainage and prostatectomy. This is followed by a chapter which deals very fully with the position of perurethral resection of the prostate. The advances made in the diagnosis and treatment of carcinoma of the prostate are discussed and the surgical control of androgen production in support of oestrogen therapy is fully described. The classification of bladder tumours and the results which may be expected from the recently introduced internal and external methods of irradiation are considered. One of the most interesting chapters is that on diversion of kidney urine, in which the various techniques of implanting the ureters into the bowel and the changes in the electrolytes of the body which will result are described, and an excellent account is given of the use of the intestine in the formation of an artificial bladder. The recent theories on stone formation in the urinary tract and the treatments which have been tried to prevent or limit their formation are fully reported. The chapters on the treatment of genito-urinary tuberculosis, the surgery of the adrenal gland, and subfertility are most comprehensive. The author and his contributors are to be congratulated on producing a book which will be of the greatest assistance to all those who have to treat urological cases.

J. E. SEMPLÉ.

TREATMENT OF LOW BACK PAIN

Joint Ligament Relaxation Treated by Fibro-osseous Proliferation. By George Stuart Hackett, M.D., F.A.C.S. Second edition. (Pp. 115+xv; illustrated. 36s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1957.

It has become so fashionable to equate low back pain with disorders of the intervertebral disks that it is refreshing to be reminded of the fact that there are other structures in the back that may cause pain and disability. Dr. Hackett reminds us that the posterior ligaments of the spine and the sacro-iliac joints were considered an important source of low back troubles some 20 years ago, and he quotes a number of cases in which he claims that he has demonstrated this to be the case. The novel feature he introduces is the idea that strained ligaments can be strengthened and the spinal joints consequently stabilized by the injection of a sclerosing fluid. Although he gives some sketchy case reports, he has not attempted a controlled study of his results and he does not disclose the precise composition of the material he injects. One might say that this book is the testimonial of an enthusiast, but the author's ideas can hardly be ignored by anyone concerned with the problem of low back pain.

J. H. KELLGREN.

RAUWOLFIA

Rauwolfia: Botany, Pharmacognosy, Chemistry, and Pharmacology. By Robert E. Woodson, jun., Ph.D., Heber W. Youngken, Ph.D., Sc.D., Phm.D., Emil Schlittler, Ph.D., and Jurg A. Schneider, M.D. Foreword by Arnold J. Lehman, M.D. (Pp. 149+xii; illustrated. 40s.) Boston, Toronto: Little, Brown and Co. London: J. and A. Churchill, Ltd. 1957.

Many have the feeling that the plants used in Chinese and Indian medicine must provide a wide field of research for valuable drugs. This idea received strong support when the alkaloid reserpine was isolated from *Rauwolfia serpentina* by Mueller, Schlittler, and Bein in 1952. This discovery has opened a new chapter in medicine and in pharmacology, and the pages of this chapter increase in number and importance year by year. A lesson may be learnt from the history of this discovery, which is that for progress to begin in the study of a plant the most certain aid is the isolation of the active principle. Withering used digitalis leaves, it is true, long before an active principle was isolated, but, unless some striking and indubitable use can be demonstrated to follow the administration of the leaves, tinctures, or extracts of a plant, a serious study of it does not begin until the active principle is found. Moreover, the isolation of the active principle by the chemists of a pharmaceutical firm means that the substance can be patented and then the whole weight of the firm can be put behind clinical trials and advertisement, so that the substance can be made widely known to the medical profession. This book, written by four authors, devotes the first 50 pages to botany and pharmacognosy, while the next 50 pages are concerned with chemistry. The pharmacology, which is the part of chief interest to doctors, is given only 28 pages, and this section, as is inevitable, is not up to date.

J. H. BURN.

BIOLOGICAL ASPECTS OF CANCER

Biological Aspects of Cancer. By Julian Huxley, F.R.S. (Pp. 156. 16s.) London: George Allen and Unwin, Ltd. 1958.

Huxley has performed the strenuous feat of compressing into a compact book of 156 pages the substance of over 500 publications on the biological aspects of cancer and on biological themes which have a bearing on cancer. It is to be regretted that the results of this Herculean task are not a complete success, one of the reasons being that too much compression soon leads to the exhaustion of the reader. Sir Julian is at his best in assembling material for the construction of a kind of intellectual cross-roads where phenomena such as plasmagenesis, virus creation, and differentiation will some day meet with the problems of carcinogenesis and the nature of neoplasia. But the author does not, of course, stop at the mere collection of facts; he has to use his scientific imagination. Nevertheless, it is debatable whether very much is gained when tumours are reclassified, from a biological aspect, into those with "genetic heterogeneity, taxonomic heterogeneity, intra-specific heterogeneity, epigenetic heterogeneity, and environmental heterogeneity"; and are we really better off when the mystery of differentiation is elaborated in terms of "pluripotent dedifferentiation, hypoplastic dedifferentiation, and anabiotic dedifferentiation"? So long as the author relies upon biological papers he is speaking with authority from his own territory; when he is dealing directly with those on cancer research he is on moderately safe ground; but when he attempts to draw conclusions or to derive generalizations or to form interpretations of neoplasia the products are not always felicitous. Cancer research has not yet had the time to arrive at the stage where theories can be formulated; it is still in its pre-Darwinian or pre-phlogiston era, and in consequence tautologies are sometimes mistaken for theories. Perhaps such a situation is unavoidable in a field where so much is still awaiting discovery.

I. HIEGER.

SOMETHING LIKE

Nothing Like Science. By Magnus Pyke. Illustrated by Michael Ffolkes. (Pp. 172. 16s.) London: John Murray. 1957.

Any reader who has heard Dr. Magnus Pyke broadcast will no doubt expect to find in this book a good deal of pert iconoclasm. So he will, and none the worse for finding what he expects. Taken in the broad, the book is informative as well as entertaining, whether the author is verging on psychology and metaphysics, as in the chapters called "The Comic Element" and "Life Automatic," or discussing more strictly practical issues, as in those on "Industrial Nutrition" and "Chemicals for Adam's Garden." Dr. Pyke is a bit of a glutton for facts, and he generally manages to regurgitate them—if I may be forgiven a somewhat physiological metaphor—in a form digestible by the young, and it is for the young in mind or in information that his book would seem to have been primarily written. Still, there's plenty in it to give to the maturer medical and other scientists something to think about, and this is as true of the book's manner as of its matter.

It is over the former, though, that I would suggest to the author some reconsideration of his attitude. In my view he does not take his debunking seriously enough. Indeed, he fails entirely to discriminate—verbally, at any rate—between solemnity, which is what he is really attacking in the open chapters and elsewhere, and seriousness, of which he himself has a more than ordinarily commendable share. This is no mere semantic distinction; it has truly been said that the British are probably the only people in the world who know, and act on their knowledge, that it is not necessary to be solemn when one is serious. And it is about the seriousness of presenting his readers always and all the time with a true picture of facts and opinions that Dr. Pyke is sometimes surprisingly cavalier. Thus to write of a virus's "organs of locomotion" (even in a jocular way); to say without at least two essential qualifications that penicillin "is employed in massive quantities as an addition to pig food or poultry food"; to call the sugar moiety of DNA "ribose"; to deprive Professor Wigglesworth of the chair he has for years so distinguishedly held at Cambridge: these are good examples of a bad habit of mind. Perhaps worse is the calm transference to human subjects of McCay's findings on laboratory albino rats; it's just not good enough to let the uninformed reader be deceived by such a statement as "the accelerating effect of the present 'high plane of nutrition' which we adopt so enthusiastically for children to-day and by which we shorten their life span" (my italics). Surely this is an occasion when a quarter, about, of the loaf of truth is unquestionably worse than no bread.

Dr. Pyke writes often with perspicacity on the part science plays, or could play, in the affairs of to-day, both material and mental or, if you like, spiritual, his attitude being on the whole humanist and rationalist, though he seems to me occasionally to cast sheep's eyes at a rather more transcendentalist standpoint. He can also write wittily. But he must beware lest his perspicacity is drowned by his wish to play the role of scientific *enfant terrible* and his wit by a markedly "upper fifth form A" sense of humour. If he does tend to try riding more than one hobby-horse at a time, moreover, the effect when they gallop off in different directions may add to the philosophically minded reader's amusement already aroused by Dr. Pyke's deliberate intent. amusements already aroused by Dr. Pyke's deliberate intent.

Because, therefore, this book can furnish us a few hours' light but instructive reading we must be prepared to overlook, look, and even to forgive, occasional lapses in grammar, style, and euphony. How anyone, though, can leave unaltered phrases such as "the instrument and nature of the scientific worker sees the structure and nature of the material with which he is dealing" and "the one illuminating fact that will spark off that flash of intuition that is the essential feature of the act of discovery" (italics again mine) just beats me. Again, Dr. Pyke must surely know that "to sleep sounder" (instead of "more soundly")

"fissionable" (instead of "fissile"), "due to" (instead of "owing to," on p. 96, l. 2), "anticipated" (instead of "foreseen" or "expected," on p. 63, para 3, l. 2) are all solecisms unbefitting a professional writer. They suggest to the percipient reader either that the author is unable to "polish up his English" or—even more regrettable—that he thinks that grammar and syntax and some stylistic graces just don't matter. Let me assure Dr. Pyke that there is no inconsistency whatever in both holding his belief about there being "Nothing like Science" and in avoiding words and constructions that are nothing like English.

A. L. BACHARACH.

GYNAECOLOGY FOR THE AMERICAN G.P.

Practical Gynecology. By Walter J. Reich, M.D., F.A.C.S., F.I.C.S., and Mitchell J. Nechtow, M.D., F.A.C.S., F.I.C.S. Second edition. (Pp. 648+xviii; illustrated. £5.) Philadelphia and Montreal: J. B. Lippincott Company. London: Pitman Medical Publishing Co., Ltd. 1957.

"This is a book designed principally for use by the general practitioner in the office practice of gynaecology." After reading the well-illustrated pages the family doctor in Britain will presume that his transatlantic colleague undertakes, and has facilities for undertaking, a much greater proportion of his own gynaecological investigations and treatments than is usual here. Nevertheless he will appreciate the excellent perspective in which the authors view the specialty in relation to the whole woman. In particular, he will glean much of value from the shrewd chapter on the "psychosomatics of gynecology" and from the sections on paediatric and geriatric aspects. There is a useful chapter on premarital counselling as in most such textbooks from the U.S.A., where, incidentally, the breasts are regarded as gynaecological appendages as well as surgical spheres. A powerful plea is made for the use of cytology smears by the general practitioner as a cancer screening test. Above all, this book provides a rich source of quotable epigrams, such as "Menstruation is a badge of femininity which may be worn in misery, pain or pride, depending on the personality of the woman"; "The brain is the centre for reception of sexual teaching, not the pelvic organs"; "The anesthetist is more important than the anesthetic agent." However, the pattern of medical practice in Great Britain is such that this book, for all its merits, is likely to be regarded here as somewhat too specialized for the general practitioner and too summary for the specialist.

S. BENDER.

GASTROENTEROLOGY FOR THE PRACTITIONER

Office Gastroenterology. By Albert F. R. Andresen, M.D. (Pp. 707+xxxiv; illustrated. 98s.) Philadelphia and London: W. B. Saunders Company. 1958.

Dr. Andresen is a senior, well-known and well-liked gastroenterologist in the United States. He has had a lifelong special interest in food allergy and in the elimination of septic foci, and his less conventional ideas have been maintained without losing the friendship and affection of his wide circle of medical colleagues in America, which is a tribute to his tolerance, modesty, and good humour. His book covers the entire field of gastroenterology, and its title of *Office Gastroenterology* has no special significance. Naturally, food allergy has a greater prominence than many would accord it, but the subject is dealt with intelligently and not aggressively. The book is written more from experience than from the literature—a not undesirable method; but it does mean that some sections are written without the perspective of recent work, and makes it less useful to the postgraduate student. It is in fact a book essentially for the practitioner, but it will be more value to American than to British doctors.

SATURDAY AUGUST 23 1958

EMOTION, EXERCISE, AND THE
ADRENAL CORTEX

Few concepts have had more impact on medical philosophy than Selye's theory of stress as a factor in the causation of disease.¹ Though most of the theory remains unsubstantiated and may even have to be abandoned in so far as it postulates an imbalance of adrenocortical secretions as a cause of "stress" diseases in man, it has at least served to draw wider attention to the mysterious role of the adrenal cortex in facilitating resistance to acute stress. Among the many so-called stressor agents are extreme cold, physical trauma, anaesthesia, anoxia, hypoglycaemia, and infections. Most of these stimuli cause a marked increase in secretion of cortisol (hydrocortisone), and patients with adrenal insufficiency may readily succumb to them by going into circulatory failure or coma unless protected by one of the glucocorticoid steroids. Until recently less has been known of the effects on adrenal function of physiological stimuli such as emotional stresses and severe physical exertion. Such knowledge may be important in relation not only to individual performance but also, if Selye is correct, to the whole concept of stress and disease.

In attempting to define the adrenocortical response to physiological assaults, difficulties have arisen such as variations in the quality of stimulus and in individual susceptibility, the problem of separating the emotional from the physical content of muscular exercise, and, especially if the response is small, the

technical difficulty of assessing changes in the rate of adrenal secretion. The eosinophil count, used in earlier studies,² is no longer reckoned to be a specific index of adrenocortical function.^{3,4} Changes in cortisol levels in the blood must be interpreted in relation to diurnal variations as well as possible changes in hepatic, metabolic, and renal function, which, by altering the rates of reduction, conjugation, and excretion of adrenal steroids, may influence the levels in the blood independently of secretion rate. Under physiological conditions the urinary output of 17-hydroxycorticoids,⁵ or preferably 17-ketogenic steroids,⁶ as measured over a 24-hour period, is now accepted as a fairly reliable index of cortisol secretion and has been applied with some success to the study of these problems.

It has been found that the emotional stresses associated with armed combat,⁷ boat racing,⁸ disturbing interviews,⁹ the anticipation of surgical operations,¹⁰ and final examinations¹¹ are accompanied by a variable rise in 17-hydroxycorticoid output, though there may be a simultaneous fall in excretion of 17-ketosteroids.¹¹ These results agree with R. I. S. Bayliss's findings of a rise in the blood level of corticoid in subjects about to present a paper before an exacting audience.¹² Except in some of the battle cases the adrenal responses obtained from emotional upset would seem to be small compared with those evoked by pathological stresses such as surgery and ether anaesthesia.¹³

Since D. J. Ingle and his colleagues¹⁴ showed that massive doses of cortisone substantially increased the work performance of rat muscle it has been of interest to know whether intense physical exertion in man would elicit an adrenocortical response. The studies of G. W. Thorn and his group⁸ on the adrenal functions of a university boat-race crew, discussed previously in these columns,¹⁵ led to recognition of the importance of the emotional factor in competitive exercise. On race days the cox and the coach both had the same increase in adrenal activity as the oarsmen, and the latter showed no response during days of non-timed practice runs.

In a recent British study from the Army Operational Research Group,¹¹ A. M. Connell, J. Cooper, and J. W. Redfearn have measured the adrenocortical response to severe muscular exercise, divorced so far as possible from emotional content. The exertions of a heavy physical training course and of a 15-mile route march caused no increase in excretion of 17-ketogenic steroids. There was, however, a small and statistically insignificant increase after two hours on a treadmill, which, as the authors sympathetically suggest, may have reflected an emotional response to

"the boredom and frustration so well known to all who have been submitted to such prolonged exercise on a treadmill."

How is one to interpret these results? The first possibility is that peripheral utilization of cortisol may be enhanced during severe muscular exercise, so that urinary excretion of the steroid and its metabolites might not reflect an increased rate of secretion. In support of this view it has been claimed that administered cortisone disappears more rapidly from the plasma, and the urinary excretion of administered cortisol diminishes, in patients with Addison's disease who take exercise.^{8,16} On the other hand, F. Ulrich and C. N. H. Long¹⁷ could find no difference as a result of exercise in the disappearance rate of radioactivity from the plasma of rats given cortisol and corticosterone labelled with carbon-14. These authors concluded that there was "little, if any, positive evidence to substantiate the concept of increased peripheral utilization of adrenocortical hormones during stress."

To summarize the present position, it seems clear that severe emotional tension can be a potent activator of cortisol secretion. If this response is devalued as a preparation for physical activity, as it could well be in a primitive environment, it would be compatible with Ingle's findings¹⁴ that cortisone enhances muscular performance. This would not imply that so natural an activity as physical exertion needs to elicit or requires an adrenocortical response, and the balance of evidence might suggest that it does not. It should now be possible with newer radioisotope techniques¹⁸ to estimate more precisely the rate of secretion of cortisol during exercise. Until more is known about the metabolic fate of adrenal hormones in peripheral tissues, the issue of whether or not their utilization is increased during stress is likely to remain undecided.

POLIOMYELITIS VACCINATION IN ONTARIO

The Minister of Health recently announced¹ plans for extending the offer of poliomyelitis vaccine to those between the ages of 15 and 25 years, and for giving a third dose to those who had already received two. The extension of eligibility for vaccination to larger groups of the population has been carried out in stages, as supplies of the vaccine increased. A similar policy has been carried out in other countries, and an informative report² from Ontario has now been published describing three years' experience with the vaccine. The first phase in Ontario began in April, 1955, with the publication of the report³ of the

successful American trial of the previous year, when it was decided to offer vaccination to schoolchildren in Ontario between the ages of 5 and 7 years. The vaccine was prepared in the Connaught Laboratories in Toronto, where notable contributions to poliomyelitis immunization have been made, including the supply of virus culture fluid for the vaccine used in the original American trial and the production of large amounts of vaccine for use in Britain. The time available before the annual epidemic season in 1955 allowed only two doses to be given, and they were administered subcutaneously with an interval of one month. Before the next poliomyelitis epidemic in 1956 it was possible to extend the offer to all elementary schoolchildren and to give a third dose to those vaccinated in the previous year. During the next year, and before the 1957 season, children under the age of 5 years were included, and also children at secondary schools. By June, 1957, it was estimated that only one-seventh of the children under the age of 18 years remained unvaccinated.

In view of the high proportion of children accepting the offer of vaccination (over 90% of elementary schoolchildren), assessment of the protective effect of the vaccine had at first to be made by comparison of the incidence of poliomyelitis in vaccinated children with that in unvaccinated children who were largely in age groups not then eligible for vaccination. The finding in 1955 of 3 cases of paralytic poliomyelitis in 309,585 inoculated children—aged 5, 6, and 7 years—and 4 cases in 362,664 uninoculated children attending elementary schools but mostly in older age groups, was inconclusive. In passing, it may be mentioned that British workers at a similar stage were more fortunate in having sufficient time to prepare a controlled trial in which the vaccine was given to a random sample of children of a wider age spread, and they were thus able to demonstrate the protective action of the vaccine.⁴ During the 1956 epidemic in Ontario more convincing figures were available than in the previous year, 5 cases of paralytic poliomyelitis occurring in 840,000 vaccinated elementary schoolchildren, compared with 71 cases in 960,000 unvaccinated children largely of pre-school and secondary school ages. By the 1957 epidemic vaccination had been offered to all children under 18 years, 1,800,000 being vaccinated and only 300,000 remaining unvaccinated. In that year there were 17 cases of paralytic poliomyelitis in the vaccinated group and 21 in the unvaccinated, the rate in those who had received the

vaccine thus being several times lower than in those who had not been vaccinated.

The diagnostic criteria used in the Ontario studies are worthy of note. All cases of paralytic or non-paralytic poliomyelitis and all cases considered to be suspects in either category were classified into one of five diagnostic groups. This classification was based on clinical signs and symptoms, including examination of the cerebrospinal fluid and virological examination of a specimen of faeces taken during the acute stage of the illness. The first diagnostic group was paralytic poliomyelitis, which was a clinical classification not dependent upon virological confirmation. To the second category, non-paralytic poliomyelitis, were assigned cases with invasion of the central nervous system and signs of meningeal irritation but no paralysis, and with demonstrable poliomyelitis virus in the faeces. The third group, non-poliomyelitic illness, included such conditions as mumps encephalitis, tuberculous meningitis, brain-stem tumour, and neuromuscular dystrophy. Numerically the largest group was that of aseptic meningitis, which was divided into two sub-groups—those with positive virus findings (most commonly of the ECHO type) and those in which no virus was found. The limitation of the non-paralytic poliomyelitis category to those with poliomyelitis virus in the faeces produced a ratio between the numbers of paralytic and non-paralytic cases very different from that usually described. In the three years of the investigation there were 121 paralytic and only 14 non-paralytic cases in the study population. During the same time 317 cases were classified as aseptic meningitis, and from 121 of these no virus was isolated.

The age grouping of the cases falling into the different diagnostic categories was also notable. Paralytic and non-paralytic poliomyelitis had a similar age incidence, but this was quite different from that of aseptic meningitis. Thus in the 1956 study, carried out when elementary schoolchildren, but not pre-schoolchildren, had been vaccinated, it was found that the number of paralytic cases in the 5 to 14 years age group was half that in the group of children under 5, and the number of non-paralytic cases at school age a quarter of those at pre-school age. These findings provided confirmation that the vaccine protected against both types of poliomyelitis. At the same time the number of cases of aseptic meningitis in the 5 to 14 years age group was more than twice that found in the pre-school group. It therefore seems possible that the inclusion of some cases of aseptic meningitis in the category of "non-paralytic poliomyelitis" in other vaccine studies has been partly responsible for the finding that the vaccine appeared not to prevent non-paralytic poliomyelitis.

RADIOACTIVITY FROM THE ENVIRONMENT

Some interesting new data have been reported by Professor W. V. Mayneord and colleagues¹ on the presence of elements of the radium and thorium series in the human body, in some animals, and in food and other substances. The method of detecting the alpha particles emitted by the radioactive elements (in ashed specimen) is a modern adaptation of Rutherford's method of counting the flashes of light, or scintillations, when an alpha particle strikes a fluorescent screen. Whereas in Rutherford's experiments the scintillations had to be counted visually, they are now detected by a sensitive photo-electric cell (a "photomultiplier") coupled to electrical counting circuits. The alpha-particle emitters of the thorium series can be distinguished from those of the radium series because they include a number of "fast pairs" of particles: one alpha particle follows another in a small interval of time as the decay of the short-lived thorium A (half life 0.14 second) follows quickly on that of its precursor thoron. When the bone specimens in the cases studied by Mayneord and colleagues had relatively high contents of radium or of radium-thorium mixtures, the method gave results in good agreement with assays made by other workers using different methods. Investigations of bone specimens from individuals exposed only to the radioactivity of the environment provided important new facts on the radioactivity of human and animal tissues.

The total alpha-particle activities of bone samples from adult London and Cornish subjects were on average respectively 0.17 and 0.50 micro-microcurie per gramme ($\mu\mu\text{C/g.}$) of bone ash, and about 60% of this activity is attributed to the radium series. These figures imply a radium content of about 0.02 and 0.06 $\mu\mu\text{C/g.}$ of bone ash for the London and Cornish subjects, and may be compared with average values ranging from 0.02 to 0.09 $\mu\mu\text{C/g.}$ in four groups of subjects in the U.S.A.² and an average value of 0.13 $\mu\mu\text{C/g.}$ for a group in Germany.³ A thorium content of about 40% of the total alpha-particle activity is high, however, compared with the findings of J. B. Hursh,² who concluded from his experiments that elements of the thorium series are not incorporated in the body in amounts comparable to the stored radium. In common with Hursh² and with H. Muth and colleagues,³ no correlation was found between radium content of bone and age. In stillborn children the bone radioactivity per gramme of ash was about the same as in adults.

A few animal bones were also included in these studies. Bones from the cow and sheep showed about ten times the radioactivity of human bone. Bones of the pig showed very little radioactivity indeed, while the single specimen from a horse had an alpha-particle activity of the same order as human bone. Whether these differences are real species differences or are determined mainly by feeding habits has not yet been determined. It is suggested that the high values of alpha-particle activity

⁵ *Brit. med. J.*, 1957, 2, 34.

found for superphosphates may have a bearing on the observed activities in cattle bones. A number of food-stuffs have been investigated, including milk; human and cow's milk have comparable radioactivity.

It is evident from the natural radioactivity found in the food chain that a few months of average diet suffice to supply an amount of radium equal to that found in the whole body. A large fraction is excreted; however, and the long-term retention is low. One human metabolic study, given in the report, indicates a possible means of obtaining more information on this problem. Results for two other substances might be mentioned; tobacco ash shows some alpha-particle activity and a pharmaceutical product had a high thorium content. Tobacco smoke, however, does not carry off the radioactivity in the tobacco ash,⁴ and pharmaceutical products can form only an exceedingly small part of the food intake. Neither of these reported radioactivities are likely therefore to add significantly to the radium or thorium content of the body. If the radioactivities reported are typical—and they appear to fall in line with measurements in other parts of the world—the radiation dose to bone is likely to be about that already calculated on an average total body burden of about 100 $\mu\mu\text{C}$ of radium.⁵ The alpha-particle activity of the Cornish bone samples would imply that the total dose to osteocytes in living bone, from all the "natural" sources, might be some 50% greater than the soft-tissue dose of 3 r in 30 years. The London samples would imply a dose about 10% greater than the soft-tissue value. Both dose rates lie within the range expected from the radioactivities in bone reported from the U.S.A. and Germany.

Until more is known about the biological effects of very small doses of radiation, it is impossible to estimate quantitatively the biological significance of the background radiation which has been present throughout man's history. If it is supposed that it is not absolutely harmless, its present magnitude must at least be presumed to be tolerable. It is important therefore to gain information about the magnitude of the "natural" radiation dose to the various tissues of the body and to investigate its variation with geographical location. The investigation reported by Professor Mayneord and his colleagues is a further step in this direction.

BUZZERS FOR BED-WETTERS

"Cures" for enuresis date at least as far back as 1550 B.C., when the Ebers Papyrus recommended a concoction of juniper berries, cypress, and beer.¹ Other less pleasant "cures" have included blisters to the sacrum, the lashing of a large frog to the child's waist, mouse pie, the sprinkling of the dried bladder of the sow over the child's bed, an instrument with a steel spike to prevent the child lying on his back, penile clamp, the application of nettles or cantharides to the glans, the application of silver nitrate to the urethral meatus so that micturition will be painful, the closure of the prepuce at night with collodion, and the passage of sounds. An interesting

invention depended on the dissolving by the urine of a tablet closing the end of a rubber tube: when the tablet was dissolved a flood of cold water or a blast of cold air awoke the child with a start. Electrical devices have been used for the "cure" of enuresis for over half a century. In the main they work either by giving the child an electric shock or by sounding a buzzer when urine is passed, thus awakening the child. Several firms now market a device of the latter variety, and writers in Britain, Australia, and the United States have testified to its value. A common type of apparatus consists of a buzzer, with a 6-volt battery, connected to a metallic rectangular gauze mat on which the child lies, preferably without trousers. When as little as one drachm (3.5 ml.) of urine is passed the circuit is closed and the buzzer sounds on the bedside table, awakening the child, who switches it off and then gets up to pass the rest of his urine. It is hoped that in this way a conditioned reflex will be established whereby the child awakens the moment urine is passed, or even before.

Since enuresis is a self-limiting complaint, with in the majority of cases a strong psychological component, paediatricians and others are difficult to convince of the value of any one form of treatment. Many widely differing types of treatment achieve something like a 60% success rate if given with sufficient enthusiasm by the doctor. In a recent paper, however, I. G. Wickes² gives a good account of the success of the buzzer in his hands, though it remains problematical how much of the success was due to the enthusiasm of the author, or to the increased age of the children after some months of treatment, or to the psychological effect of the apparatus rather than to the establishment of a conditioned reflex. Wickes selected 109 consecutive intractable cases of bed-wetting for study. In four cases the parents refused to report progress; in two cases the children refused to use the apparatus; two parents could not manage it; and one child stopped bed-wetting before the apparatus was set up. This left 100 children for study, of whom 81 were boys. Seventy-four were aged 7 to 13, 12 were aged 14 to 17, and only 12 were under 7. Children with enuresis of moderate severity (50–75% wet nights) responded best to this treatment, for 89% of this group became dry during the third month of treatment. Fifty of the 100 children in the whole series responded rapidly and completely; 15 dried up almost completely; 9 improved markedly but slowly; and 26 failed to benefit. Nine of those successfully treated relapsed, but 8 of these again responded rapidly and completely to a further course. Wickes noted striking emotional improvement in those who benefited.

The buzzer device has some disadvantages, which should be recognized. First, it is expensive. The cost of some of the apparatus on the market certainly seems to be excessive, for a good hospital engineer should be able to rig up a machine at one-fifth of the cost of some of those now advertised. The apparatus is somewhat complex, and less intelligent parents may have difficulty in making it work; it can be used only by one patient at

¹ Quoted by Glicklich, L. B., *Pediatrics*, 1951, 8, 859.

² Wickes, I. G., *Arch. Dis. Childh.*, 1958, 33, 160.

a time, and it requires the intelligent co-operation of the child. Wickes does not recommend it for use by children under 7. Lastly, it may take many weeks to establish the conditioned reflex. Nevertheless enuresis is a very distressing condition for parents and psychologically disturbing for children. If all other reasonable methods fail in older children there is much to be said for giving the buzzer a trial.

ARTHRITIS IN ULCERATIVE COLITIS

Arthritis is one of the more common complications of ulcerative colitis. Two representative British series^{1,2} have given figures of 5.4% and 13% respectively, while a recent American series gave a figure of 22%.³ E. G. L. Bywaters and B. M. Ansell⁴ have now published a valuable study of this special form of arthritis based on observations made on 37 patients with the condition. The joints most frequently affected were the knees and ankles, while the finger-joints were less commonly attacked than in rheumatoid arthritis. The toe-joints were affected in four patients, sometimes with involvement of the distal interphalangeal joints, which is rare in true rheumatoid arthritis. Disease of the sacro-iliac joints, indistinguishable radiologically from that seen in ankylosing spondylitis, occurred in six patients.

The characteristic course was of a recurrent mild synovitis, at first attacking one or two joints, which subsided as others were affected. This migratory polyarthritis initially caused the illness to be diagnosed as rheumatic fever in some of the patients. The arthritis was fairly frequently associated with skin lesions, especially erythema nodosum, as noted in earlier studies.^{1,5} The arthritis commonly bore a positive relationship to the colonic symptoms and usually cleared up when the colitis subsided, though this was not invariable. In some patients irreversible changes took place in the joints, with limitation of movement as a sequel. The radiological changes were sometimes the same as in rheumatoid arthritis, but patients with severe or prolonged joint disease might show periostitis and erosions of the joint cartilage, sometimes extensive enough to result in complete loss of cartilage and ankylosis. Biopsy specimens taken from synovial membranes in three patients had histological appearances similar to those seen in rheumatoid arthritis. The Rose-Waaler test was persistently negative in 25 out of 29 of these patients. Among the other four, in one case the test was positive on one occasion but negative on a second; one case maintained a positive test in the complete absence of joint symptoms; while the other two cases, with persistently positive Rose-Waaler tests, were clinically identical with classical rheumatoid arthritis. These serological findings are important in showing that the majority of the patients with both arthritis and ulcerative colitis are not suffering from classical rheumatoid arthritis. In other words, either the arthritis of ulcera-

tive colitis is secondary to the diseased bowel, or ulcerative colitis can be regarded as a generalized disease in which the diseased bowel is only one, though the most important, of the manifestations.

Among the patients who were treated surgically, colectomy (or ileostomy alone) brought about subsidence of the joint symptoms in the large majority, a finding which agrees with previous observations.² Likewise, successful treatment of the colitic symptoms with cortisone and its analogues was accompanied by relief of the arthritis in seven out of the eight patients so treated. The results of surgery are perhaps the strongest evidence in favour of the view that the arthritis of ulcerative colitis is usually no more than a secondary consequence of the diseased bowel.

ACUTE EPIGLOTTITIS IN CHILDREN

Acute respiratory diseases are exceedingly common in children, particularly in winter. The clinical picture varies greatly according to the situation of the lesion, the organism causing it, and the age of the child. Most of these diseases are well recognized, but there is a relatively rare condition in this group which is little known yet which presents a most dramatic clinical picture, often leads to sudden unexpected death, but responds well to prompt treatment. This condition is acute epiglottitis. It seems to be a specific condition almost invariably due to an infection by *Haemophilus influenzae* type B. It occurs in children of all ages, though its peak incidence is at about 4-5 years of age, or rather above that of the commoner acute laryngotracheobronchitis on the one hand and of *H. influenzae* meningitis on the other. It may appear in small epidemics, several cases being seen in one year, and very few in others.

The condition was perhaps first recognized as distinct in France¹ and its first description in the English language came from S. E. Sinclair,² of Yale University, who described ten cases in 1941. Several American reports followed³⁻⁷ describing up to twenty cases in each series. Little has been written on the subject in the British literature. S. de Navasquez⁸ described a single case, and later F. E. Camps⁹ and H. Morris Jones and Camps¹⁰ described a series of cases. These articles, and a recent paper by W. Berenberg and S. Kevy,¹¹ of Boston, give an excellent description of the condition.

The illness follows a typical clinical course and has unique and diagnostic physical findings. Nevertheless, Berenberg and Kevy report that only once was the correct diagnosis made before admission to hospital in their 42 cases, and most of Morris Jones and Camps's 29 cases came to necropsy after being reported to the coroner as sudden unexpected deaths. The onset of the

illness is sudden, with difficulty in breathing, severe sore throat, and fever. There is a degree of shock out of proportion to the short duration of the respiratory difficulty. The illness then rapidly progresses. Twenty-two of Berenberg and Kevy's patients were admitted within eight hours of the onset and three were dead on arrival less than six hours after the first symptoms. Later symptoms include dysphagia, retention of secretion in the nasopharynx, and hoarseness with stridor. The onset of the shock-like state may appear unexpectedly. On physical examination the cardinal sign is the extreme swelling of the epiglottis, which on deep depression of the tongue is seen to be fiery red, bearing a striking resemblance to a bright red cherry obstructing the pharynx at the base of the tongue, though the rest of the pharynx may only show slight inflammation. *H. influenzae* type B can usually be cultured from swabs taken from the epiglottis and was also found in the blood in 11 out of 16 of Berenberg and Kevy's patients so investigated.

The most effective treatment in all series was tracheotomy. Though not always essential, the doctor in charge has to be ready to perform it at a moment's notice. Children with this disease should be taken to hospital without any delay, as the course, if untreated, is usually rapidly disastrous. Five of Berenberg and Kevy's patients died and none of them had had tracheotomy. Supportive and antibiotic therapy is of some help, and chloramphenicol is favoured as the drug of choice in doses of 50-100 mg. per kilogram body weight daily.

THE N.H.S. IN 1957

The customary amount of detailed information on the deployment of National Health Service resources, material and human, is contained in the 254 pages of the Annual Report¹ of the Ministry of Health for 1957. The report appears earlier this year than it has done since the N.H.S. came into being. The total cost of the Service, £585m., was about £50m. more than for the previous year, and about £29m. of this £50m. was accounted for by an increase in cost of the hospital and specialist service. Some four-fifths (£468m.) of the total cost was met by the Exchequer, and the remainder was met by local rates (£24m.), by charges to patients (£28m.), by superannuation contributions and transfer from the values (£28m.), and by the contribution from the National Insurance Fund (nearly £37m.). Since September, 1957, the latter source of income has been replaced by a separate fund set up under the provisions of the National Health Service Contributions Act, to which patients pay double the former weekly amount and which in a full year will bring in roughly £80m., thus reducing the proportion of 80% of the cost borne by the Exchequer in 1956-7 to an expected 76½% in 1957-8.

The number of prescriptions dispensed fell by about 21m. compared with the previous year, but the cost rose by over £4m. to £60,851,903, and the average cost per prescription rose from 4s. 11.57d. to 5s. 10.48d. It is estimated that the corticosteroid drugs accounted for

9.7% of the cost of the ingredients of prescriptions, and the advent of the more expensive prednisone and prednisolone in February, 1957, had a marked effect on this item in the drug bill. Antibiotics, by far the most expensive category of drugs, accounted for 19.94% of the total ingredient cost.

The number of patients treated in hospital rose by some 54,000 to 3,793,000, but by the end of the year about 440,000—9,000 more than a year earlier—were awaiting admission. Disorganization caused by the influenza epidemic may well have been partly responsible for this disappointing lengthening of the queue, which had moved along at a record speed in 1956. Those waiting for general surgery and ear, nose, and throat surgery accounted for more than half the total waiting-list, and about one-eighth were gynaecological cases. But this waiting-list position varied markedly in different regions, being highest in Oxford but actually improving in Manchester and Liverpool. The number of in-patients treated was 29% greater than in 1949 and this was achieved with only 6% more beds than were available at the beginning of the Service. £18m. was allocated for capital development in 1957-8, and during the year work began on new hospitals in Hensingham in Cumberland, Swansea, Swindon, and Welwyn. The number of consultants employed was 6,902, compared with 6,739 in the previous year and 5,649 in 1950.

The number of general practitioners practising as principals in England and Wales increased by 261 to 19,343, of whom 12,962 were working in partnerships. The average number of patients per doctor remained much the same at 2,273. Hearings by medical service committees of complaints against doctors and subsequent recommendations by executive councils to the Minister were fewer. In 243 cases, out of a total of 328, no breach of the terms of service was found. No doctor's name was removed from an executive council list; disciplinary action in the form of withholding money was taken in 31 cases, and 38 warning letters were sent.

A rising birth rate was reflected in an increase in activity of the domiciliary and welfare services of local authorities. Domiciliary midwives attended 255,747 confinements, 8,104 more than the year before. In 205,934 (81%) of these cases a doctor was booked, and a doctor was present at delivery in 44,878 of them. Visits by home nurses increased from 24,652,655 to 25,053,813. Some of this increase may have been due to the influenza epidemic, but attendance upon the elderly was mainly responsible. Likewise the aged and chronic sick continued to make the greatest demand on an expanding domestic help service. 1,222,136 children under 15 were vaccinated against poliomyelitis in 1957, and a further 1,754,744 were registered and awaiting vaccination at the end of the year. Only 43% of infants were vaccinated against smallpox and only 48% immunized against diphtheria.

We record with regret the death at Philadelphia on August 16 of Dr. Chevalier Jackson, whose notable contributions to bronchoscopy won him honours all over the world. He was 92 years of age.

WHY ARE MEDICAL JOURNALS SO DULL?

BY

RICHARD ASHER, M.D., F.R.C.P.

Physician, Central Middlesex Hospital, London

Medical journals are dull; I do not think there is any doubt about that. There are many causes of their dullness; some are curable and some incurable. I do not separate them: this is a short study of the pathology, not a dissertation on the prophylaxis and treatment, of the condition.

Wrappers and Covers

Their wrappings are drab and difficult to remove, so the journals accumulate on our desks in inconvenient piles and roll on to the floor. There is little incentive to make the effort of opening them. When opened they have a strong tendency to roll themselves up again.

The covers are as drab as the wrappers. There is nothing on the cover to distinguish one copy from another or to titillate the clinical appetite. There is in some journals a table of contents on the outside page, but the titles are so discouraging that they provide very little incentive for reading the journal, especially to a man already weakened by the effort of unwrapping and correctively re-rolling the twisted pages. In other journals the table of contents is hidden among the first few pages of advertisements. Advertisers pay more if their wares are inserted half-way through the programme, as in commercial television, and so while hopefully scanning the contents one is interrupted by a vasodilator or a purgative. With the *Proceedings of the Royal Society of Medicine* I have quite often missed something because an advertisement made me think I had finished the list of contents.

Titles

Many of the titles are unattractive. Without going in for sensationalism an author can try to make his title allure as well as inform. A medical journal is an open market where each salesman must cry his goods if he wishes to get an audience at his stall. A poor title dulls the clinical appetite, whereas a good title whets it. I have called this article "Why are Medical Journals so Dull?" I do not claim this title is specially good, but it is better than "A Study of the Negativistic Psychomotor Reactions induced by Perusal of Verbalized Clinical Material." Titles such as "A Trial of 4,4-Diethyl-hydro-balderdashic Acid in Acute Coryzal Infections" are far better changed to "A New Treatment for Colds."

An important addition to the title should be the author's name, which may attract or repel according to the reputation he enjoys; but medical articles to-day appear to be often written by committees, and this multiple authorship is highly discouraging to readers. Ten men cannot write an article any more than ten men can drive a car. The interest evoked by an author's name is diluted by listing all his advisers.

Wanting in Colour

So much for the cover. Now for the inside. The paper is often of poor quality, and coloured pictures are almost unknown. I realize it is economically impossible that this should be otherwise, but medical journals contrast so glumly with the glossy productions of the big drug houses or with women's weeklies.

The advertisements in medical journals are essential to add revenue, but they add little else and seem far less exciting than the advertisements in lay weeklies. Prosperous people

in brightly coloured dresses sipping expensive drinks in luxurious liners provide us with happy daydreams of holidays we cannot afford. Advertisements in medical journals are quite the reverse: elderly men in shabby pyjamas hurrying along the passage with urinary frequency. They are not attractive; nor are the other afflicted persons pictured there with tension, hypertension, insomnia, and pain. Humorous advertisements in medical advertising are rare; it might be cheering to see a strip cartoon of the doctor whose practice dwindled because of night starvation but rose with dramatic success after Horlicks; or the physician who found his failure to be elected to Fellowship was due to his not using Amplex.

In short, there are many factors which dull the prospect of reading a medical journal even before the letterpress is reached: the wrapping, the unwrapping, the titles, the authors, and the advertisements. There are additional psychological deterrents—the feeling of duty: "I ought to read this, for my exams; for my edification; to keep up with my houseman; because my patients will read it in the *Reader's Digest*; or because George will ask me what I think of it. Duty, if one is aware of it, is usually a deterrent, but it is also associated with the idea that a lot of what you don't fancy does you good.

A Tedious Duty

Now for the letterpress itself. It is inevitable that editors have to accept a certain amount of junk both to fill their papers and to avoid giving offence to eminent medical men. For many doctors the achievement of a published article is a tedious duty to be surmounted as a necessary hurdle in a medical career. You have got to get over it, just as you have to dissect a dogfish for the first M.B.; you don't like it, but it's got to be done. Though the subject of an article is important it is not much to do with its dullness. I believe if a man has something to say which interests him, and he knows how to say it, then he need never be dull. Unfortunately some people have a desire for publication but nothing more. They have nothing to say, and they do not know how to say it. They want to be seen in the *British Medical Journal* or the *Lancet* because it is respectable to be seen there, like being seen in church. They would stand no chance of publication in lay magazines, but the number of medical magazines is so large that every dull dog has his day. Often there seems to be a spate of articles on the same subject; for example, intervertebral disks were all the rage some years ago, whereas hiatus hernia is much in the news to-day. Other subjects, especially in the correspondence columns, flower, like cacti, every two or three years; for instance, discussions on herpes zoster and chicken-pox, or on the correct use of "tropic" and "trophic."

Good Presentation

The dullness of an article depends much on its presentation—that is, the way it is set out, the order in which the facts are put, and the way the diagrams or pictures are arranged. It is astonishing what a difference this makes. For example, here are two ways of setting out one case. A man was crushed by a bombed building, injuring his diaphragm. He consequently developed a right diaphragmatic hernia which resulted in dyspepsia from visceral displacement. Surgical repair of the hernia relieved his symptoms.

That account is factual and accurate, but not especially interesting. Here is the same case as I heard it described by the surgeon at a meeting of a clinical section. He operated on a man who had symptoms of duodenal ulcer, and to his chagrin was unable to deliver the duodenum. At length his exploring hands disappeared into a large hole in the right diaphragm, where he found much intestine. There was no duodenal ulcer. He then reviewed the chest x-ray film and found that the alleged thickened pleura was really hernia and that gas could be (and should have been) recognized in it. As soon as the man came round from the operation a fresh history was taken, and it was found that

the pain was nothing like ulcer pain; it had no periodicity (it had been caused by the duodenum being stretched across the lumbar spine). Also, the history of the crush injury was elicited; until then it had not been discovered. The surgeon concluded: "The moral is that one ought to take a history before the operation rather than after it."

You will agree that this second version is live; the first was dead. The first was chronological and factual, yet was tidied up so much that there was no interest left: it had the dullness of a sieved diet.

May I mention a recently published case of my own, "A Woman with the Stiff-man Syndrome"? Here I wrote the account of events not in chronological order but in logical order, starting with my reading an annotation on this syndrome, then my realizing I had seen a case of it ten years drome, then a search for the lady, followed by a re-previous view of the notes, and finally a description of her behaviour at a clinical meeting. I thought this would make the article more alive. This device of telling a story by starting in the present and darting to the past and back is far from original, yet to my surprise I received a large number of approving letters and telephone calls praising the way the article was written. I did not know so many people minded about presentation. The amount of comment produced when trouble was taken to make the presentation as interesting as possible suggests that the average contribution may be rather dull in presentation and that a lively commentary shines like a good deed in a naughty world. I am sure many people writing for medical journals would take more trouble if they knew how much difference it made.

To refer to an article of my own in the above paragraph may suggest I am immodest. That is a risk of using the first person. Yet avoiding "I" by impersonality and circumlocution leads to dullness, and I would rather be thought conceited than dull. Articles are written to interest the reader, not to make him admire the author. Over-the-conscientious anonymity can be overdone, as in the article by two authors which had a footnote, "Since this article was written, unfortunately one of us has died."

An important factor in presentation is the use of diagrams, charts, tables, and so on. I often find that I cannot understand diagrams in medical journals even when I try very hard. I take several minutes identifying the ordinates and sorting out the different types of hatching and shading and their interpretation. Then I usually find I have been looking at Fig. 1 instead of Fig. 2. A diagram should be used only if it makes something easier to understand. The purpose of a diagram is not to crowd as many facts as possible into the smallest space.

Style

Style is what matters most; grammar, syntax, spelling, and punctuation are only useful conventions; they matter very little, nor need we disapprove strongly about improper unions between Greek and Latin or we would have to say dicycle instead of bicycle. What *does* matter is when doctors write what Ivor Brown calls "pudder" and Sir Ernest Gowers calls "gobbledygook." They clog their meaning with muddy words and pompous prolixity; they spend little time in seeking the shortest, neatest, and plainest way of putting down their meaning. Quiller-Couch, A. P. Herbert, Ivor Brown, and Sir Ernest Gowers have done a great deal to encourage good writing, but I think Sir Ernest Gowers's *Plain Words* is the best of all. Unfortunately those who need it most read it least, because anyone taking trouble to buy a book about using English will probably take trouble in writing it: style is largely a matter of taking trouble, though many people wrongly regard it as a gift. The people who write badly do not seem to realize they do, and so do not buy this admirable book.

Here is a sentence from a medical journal: "Experiments are described which demonstrate that in normal individuals the lowest concentration in which sucrose can be detected by means of gustation differs from the lowest con-

centration in which sucrose (in the amount employed) has to be ingested in order to produce a demonstrable decrease in olfactory acuity and a noteworthy conversion of sensations interpreted as a satiety associated with ingestion of food." All the author meant was: Experiments are described which show that normal people can taste sugar in water in quantities not strong enough to interfere with their sense of smell or take away their appetite.

Lastly, length. Medical articles should, like after-dinner speeches, finish before the audience's interest has started to wane. I finish now, pointing out that this paper, like the talk on which it is based, is only intended to provoke discussion. It solves no problems; it only poses them. It is incomplete, inaccurate, and probably irritating; but I hope—and I have spent many hours trying to achieve that end—that it is not dull.

STOOL-GAZING

BY

S. LEVIN, M.B., M.R.C.P.Ed., D.C.H.

Johannesburg

Jack Sprat could eat no fat.—Nursery rhyme.

This cryptic line gives us no reason for Jack's inability to eat fat. In tracing the origin of this ditty, however, we learn that the term "Jack Sprat" was used in the sixteenth and seventeenth centuries to denote a dwarf. Could it be that some prophetic individual had anticipated Samuel Gee (1888), and had unwittingly described coeliac dwarfism? Did a high-fat diet upset Jack Sprat's bowel habits? Did it cause diarrhoea?

The stools are like the skin, being readily visible, frequently examined, accessible to study and scrutiny, subject to loathsome and malodorous diseases, and filling the subject and onlookers with horror and disgust.

A Disappearing Art

To a discerning physician it is clear that the art of stool-gazing is rapidly passing into oblivion. Indeed, the last half-century has seen a phase of stool scrutiny in clinical and social paediatrics the magnitude of which should not permit of its passing without notice and without epitaph. Until very recently infants' stools had been studied with a devotion paralleled only by the passionate zeal with which the Babylonians studied the liver and divined the future therefrom. The ancients cast an inquiring glance even at the stools. Aristotle, for example, held that meconium (Gr. *mekon*—poppy) was the substance responsible for keeping the infant asleep *in utero*. Throughout history various preparations of stools have been used for medicinal purposes (*Drekapotheke*). But it is only in the last fifty to seventy years that divination by stool has become widespread in the medical fraternity. "In no branch of paediatrics," writes Fischer (1928), "has so much progress been made in recent years as in the study and interpretation of infant feces."

In the autumn of 1950, during my first house job in paediatrics, I was introduced to the art of stool-gazing. Every Friday morning the medical staff congregated in the sluice-room, where a stool specimen in a labelled diaper was placed before us by the nurse in charge. All the infants were represented by their stools. These were solemnly studied, spread out with a spatula, colour, curds, and consistency noted, and a decision was made regarding a change in the infant's diet. Perhaps the sugar content of the feed was reduced, the water concentration altered, the protein changed, and the formula was thus "tailored" to fit each particular infant. Thus were digestive difficulties

dealt with. In the words of Southworth (1907): "When difficulties arise, a trial is made of a new mixture, which is poured in at one end of the infant's digestive tract, to be submitted to the mysterious alchemy of complex and dimly outlined digestive processes, and the outcome is anxiously awaited at the other end to spell success or failure."

The first timid and tentative steps in stool-gazing were taken in Europe some 70 years ago when Biedert began to take notice of feeds and faeces, the "intake-output complex." In the 1910's and 1920's the cult, then graced by the term "clinical coprology," reached its zenith, particularly on the Continent. There was preoccupation with the stools almost to the exclusion of the infant who passed them. Truby King (1918), for example, agreed with the dictum that "the first question in almost every disease in children should be, 'What are the motions like?'" Indeed, he agrees that "if we could keep the motions always normal, we should have very few or no delicate children."

To-day the threescore years and ten of the stool-gazing fraternity is all but over. It is the end of an era, but not quite the end. Many nurses, for example, are still much concerned with the condition of the stools, and even intelligent mothers are terrified of "green diarrhoea," and change an infant's feed at the slightest sign of a green stool. Some unfortunate infants are fed on black tea or glucose-water for days on end, for no other reason than that their stools are greenish or loose. Mothers not only believe that their offspring must have satisfactory daily evacuations, but the popular press, intent on selling various nostrums, fosters this delusion. "Don't forget," warns an official Canadian Government booklet, "that a baby's bowels need regular attention" (Couture, 1950). Rather like the regular lubrication needed by an automobile engine. "The poor intestines," wails Bergen Evans (1947), "victims of a thousand theories, are convulsed by poisonous drugs, drenched with mineral oils, and lacerated by roughage until they frequently abandon all effort to function." Truby King insisted on a daily bowel movement with a fervour so intense that its necessity might have been inscribed on the very Tablets of the Law handed down on Sinai. Hill (1922) was prepared to allow an infant a latitude of 48 hours. To-day the public still has difficulty in understanding a doctor who evinces little interest in a baby's stools.

Philipp Biedert (1847-1916) was the first to study milk in relation to infant nutrition. He gave great impetus to consideration of the food-faeces relationship, the "intake-output complex." Presently the various dyspepsias, indigestions, intolerances, and intoxications held sway throughout the paediatric world. Biedert believed that the casein of cow's milk was largely indigestible and gave rise to casein curds in the stools of infants who were not thriving. He therefore developed "rhamgemente" (cream mixture) in 1883, this substance having but 1% protein.

Minor Shrines

Further observations on stools indicated that "casein curds" were in fact made of fat rather than protein. Early in the 1900's Czerny and Keller confirmed this, and blamed the indigestibility of fat for "Milchnährschaden" (milk injury). An enormous clinical edifice was erected based on the alleged menace of fat, this citadel all but tottering to-day. At various times excess of carbohydrate, salts, and protein were also held as being deleterious to infants and being responsible for various types of indigestion and dyspepsia. Many physicians worshipped at these minor shrines. The laity still fear sugar in an infant's diet, somehow linking it with diarrhoeal stools. Sugar dyspepsia has been thought to give rise to loose, frothy, sour-smelling stools. Firm remnants of such conceptions are still to be found in many paediatric textbooks. A recent popular textbook for students (Sheldon, 1955) has five pages devoted to an account of carbohydrate, protein, and fat indigestion and their characteristic stools, these factors being dealt with in such a convincing manner that one is almost tempted to believe that such pathological conditions exist.

While excess of protein has been thought to occasion constipated stools, excess of fat has sown confusion in the clinical ranks. Some authorities blame it for causing both diarrhoea and constipation—and this, moreover, in the very same breath, the very same paragraph. In this category there are, for example, Brennemann (1923, p. 639), Morse (1926, p. 158), Cautley and Paterson (1929, p. 40), and the official publication of the Ministry of National Health and Welfare of Canada (Couture, 1950, p. 149). Paterson and Newns (1955) have the good grace to uphold one view on page 70, and to assert the contrary view on another (p. 113).

Modern views in fact stress the opposite of that believed by earlier generations of paediatricians. Trouble occurs, not from having too much of any particular constituent, but too little. The whole concept of "tolerance" for food is based on very shaky foundations, as is evidenced by the perfect ease with which most infants deal with "solid food" even when but a few weeks old. When intolerance does occur in the infant, as likely as not it will be due to a specific sensitivity to a protein, such as lactoglobulin (Davidson and Burnstine, 1957).

Changing Views

An account of changing views on the oral management of diarrhoea has been dealt with in another paper (Levin, 1958). The study of the physical state of diarrhoeal stools (clinical coprology) held many of the earlier paediatricians in thrall. In the presence of diarrhoea, endless discussions revolved about what exactly in the diet was excessive, irritating the gut, and could thus not be tolerated by the infant. As an example of all-embracing obfuscation, the following extract (Fischer, 1928) would be hard to beat: "A new conception of the various food elements shows that the opinion of ten years ago regarding the dangers of high fat has been modified, and the possibility of a protein or casein element being the disturbing factor suggested. Modern science has proved beyond a doubt that one reason why the fat or casein disagrees is due to the presence of milk sugar; hence we to-day regard the carbohydrate and salt as the disturbing element in many cases, rather than the fat or casein." With such confusion about the noxious element in milk, it is not surprising that all constituents were often restricted in the treatment of loose stools, and infants were starved (indeed, still are) sometimes for days on end. Moreover, insult was added to injury by the common administration of a cathartic; and enemas to help clean out the poisonous stools were also given, thus exposing the infant to collapse from electrolyte imbalances.

Yet even from the beginning some hardy and sceptical souls raised objections to clinical coprology, to the prognostications based on stool-gazing, and to the methods of treatment based on the appearance of the stool.

As early as 1917, Grulee averred that he did not give castor oil for diarrhoea. Morse (1926), in all fairness, thought it only right to mention that some paediatricians regarded clinical coprology as a waste of time. Edwards A. Park (1923) decried the practice of starving infants merely because of loose stools; so did Hess (1930); and also Jeans and Marriott (1947), who wrote: "When attention is focused on the digestibility of the food and character of stools the energy needs are often overlooked." Wright (1934) stated: "The overemphasis on the study of the stools is a myopic method of estimating disturbances of nutrition in infancy."

The earlier views of Finkelstein (1910's) indicted carbohydrate and salts as causing dyspepsia in infants. He therefore devised a (protein) milk in which the concentration of these two constituents was greatly reduced. By decreasing the concentration of soluble salts (sodium and potassium) he hoped that the relatively higher proportion of insoluble salts of calcium and magnesium would combine with fat to make firm insoluble soaps and thus give bulk to the stool. Of course, the low concentrations of sodium and potassium did not do much to help sick infants who were already lacking these ions following on loss via vomiting

and diarrhoea. Moreover, one lesson has still not been learnt by the "low-fat feeders," and it is this: the consistency of stools is largely dependent on saponification of fat and production of insoluble soaps, and that one cannot make soap without fat any more than one can make bricks without straw (Goldbloom, 1957).

Conclusion

The final crushing blow to clinical coprology is the undoubted fact that the study of stools is now largely in the realm of laboratory investigation. The textbook by Moncrieff and Evans (1953), for example, has two pages devoted to "Faeces in Children"; they are not to be found in the chapter on feeding, however, but under the heading of "Clinical Pathology." So that clinical stool-gazing has now left the province of the paediatrician and has entered the domain of the biochemist and bacteriologist.

It is altogether fitting and proper that we should recognize the end of the allotted span of threescore years and ten to the clinical cult of coprology; and that we should dispatch the remains of this cult to the limbo of forgotten things. The era of the stool-gazers and stool-diviners is past.

EFFECTS OF ATOMIC RADIATION UNITED NATIONS REPORT

In a leading article last week (p. 433) we commented on the recently issued Report of the United Nations Scientific Committee on the Effects of Atomic Radiation. We print below a brief summary of this report and of a statement about it published by the Medical Research Council.

When the United Nations committee was set up in 1956 it decided to examine the matters falling within its field of competence under the following five main headings: (a) genetics, (b) the effects of irradiation by internally absorbed isotopes and the effects of external radiation, (c) natural radiation levels, (d) exposures during medical procedures and occupational exposures, and (e) environmental contamination. After describing the basic physical concepts—types of radiation and units of measurement—and basic biological concepts—including the somatic and genetic effects of radiation—the report examines the natural and man-made sources of radiation. As to the latter, more than 80% of the genetically significant dose from diagnostic x-ray exposure is contributed by six or seven procedures (those involving the region of the lower abdomen and pelvis), but these procedures constitute only about 10% of all examinations. "For countries with an extensive use of x rays, the average annual marrow dose of the population can be estimated to range beyond 100 mrem per person. This figure is very close to the *per capita* marrow dose from natural radiation. . . . A reduction in dose might be achieved

by a further consideration by the medical profession of the circumstances in which x-ray diagnosis is appropriate. This could be facilitated by statistical information on the importance of each examination chosen for the reduction of any specific morbidity. Administrative co-ordination between authorities who require that certain examinations be made in the routine health surveillance of whole populations or special groups, such as schoolchildren, students, employees, could well be improved."

Contamination of the environment by radioactive fall-out as a result of nuclear explosions is examined in detail. Extensive information on the strontium-90 and caesium-137 concentrations in soil, plants, animal and human foods, and in human beings was received by the committee, which concluded that there were no practical methods of preventing the entry of these radioisotopes into the human body once they had been released into the environment.

Radiobiology

On the subject of fundamental radiobiology the report states that "the succession of events which take place between the time of irradiation and the appearance of recognizable effects is very intricate. . . . The lack of fundamental knowledge of normal cell structure and function is in our opinion the major factor limiting progress in radiobiology." The major problems on which radiobiological research is needed include: (1) the nature of the primary damage to cellular structures and the pathways of expression of this damage; (2) the dose-effects relationships at low dosages; and the mechanisms of chemical protection and recovery.

The chapter on the somatic effects of radiation covers physical factors, general pathology and special pathology, including such possible delayed effects as shortening of the life-span and the production of cancer. "Clinical and experimental evidence show that where the total body is irradiated, leukaemia is the most probable end-result among the various forms of malignant disease." After calling for continuing research in all aspects of radiation, the report states: "At the present time, due to the fact that delayed somatic effects of radiation are not exactly known, it must be recognized that the exposure of human populations to increasing levels of ionizing radiation may cause considerable and widespread somatic damage."

The genetic effects of radiation are considered in a short chapter, backed up by a much longer technical appendix. A dose of between 10 and 100 rads per generation would probably be required to double the natural mutation rate in human populations. "About 4% of all births are affected with hereditary disorders, some one-quarter of which appear to be at least largely determined by single gene differences. On this basis, an increase in the mutation rate would eventually result in a directly proportional increase in a part of this 4%, amounting to more than one-quarter, but less than the whole of it."

From world-wide averages the committee has computed the estimated dose from different radioactive sources under two headings—genetically significant dose and *per capita* mean marrow dose. Varying figures are given for environmental contamination depending on if and when weapon tests cease.

In its general conclusions the committee states that all applications of x rays and radioactive isotopes used in medicine for diagnostic purposes and for radiation therapy are for the benefit of mankind and can be controlled. Radioactive contamination of the environment resulting from explosions of nuclear weapons constitutes a growing increment to world-wide radiation levels. This involves new and largely unknown hazards to present and future populations; these hazards, by their very nature, are beyond the control of the exposed persons. The committee concludes that all steps designed to minimize irradiation of human populations will act to the benefit of human health. In an attempt to assess the possible effect of natural and of fall-out radiation in causing leukaemia, tumours of bone, and major genetic effects, the committee has prepared the accompanying table. After describing the wide gaps in knowledge about the biological effects of radiation, the

Estimates of Certain Possible Annual Consequences of Radiation Received by World Population from Certain Sources

Consequence	World Population Assumed (in Millions)	Natural Occurrence Assumed Per Year	Source of Radiation		
			Natural Radiation	Fall-out from Weapon Tests	
				Tests Stopping in 1958	In Equilibrium After Prolonged Continuation of Tests
Leukemia:					
If threshold 0 rem	3,000 5,000	150,000 250,000	15,000 25,000	400 to 2,000*	— 5,000 to 60,000
If threshold 400 rem.	3,000 5,000	150,000 250,000	0† 0†	0‡ —	— 0§
Major genetic defects	5,000	700,000 to 3,000,000	25,000 to 1,000,000	**	500 to 40,000

* Maximum rate during peak period. An estimated total of less than 25,000 to 150,000 would ultimately occur.

† Unless individual bone-marrow dose exceeds mean value by a factor of 60.

‡ Unless individual bone-marrow dose exceeds mean value by a factor of 80 to 500.

§ Unless individual bone-marrow dose exceeds mean value by a factor of 5 to 60.

** A total of 2,500 to 100,000 would occur over subsequent years.

report concludes: "The advance of research in all these fields depends upon appropriate training of scientific workers."

MEDICAL RESEARCH COUNCIL'S COMMENTS

Within six days of the publication of the report of the United Nations Scientific Committee, the Medical Research Council had prepared and published a statement¹ on it. For this expeditiousness Lord Limerick, the chairman of the M.R.C., pays tribute, in his introduction to the statement, to the committee responsible for it—the same committee as had been appointed to report² on the hazards to man of nuclear and allied radiations, under the chairmanship of Sir Harold Himsworth. In the opinion of the M.R.C. committee the U.N. report is "both a valuable account of present knowledge in this field and an important contribution to the difficult problem of its assessment." In general, the U.N. report has strengthened and amplified the tentative conclusions and predictions of the two earlier reports, that of the M.R.C. and that of the United States National Academy of Sciences.³

Somatic and Genetic Effects of Radiation

On the fundamental problem of the relationship between radiation dose and the effect which may be produced on human populations, the M.R.C. statement agrees with the view that for every small increment of exposure to radiation there is a small but proportional increment in the frequency of mutations in the germ cells that will manifest themselves as genetic changes in future generations, and that there is no threshold dose below which no such effect occurs. But, the statement says, scientific opinion is still divided as to whether a threshold dose exists below which there will be no induction of leukaemia or other forms of cancer. Though the U.N. committee plainly accepted this, nevertheless the M.R.C. committee felt there was a predisposition in the report "to favour the view that the induction by radiation of such long-term somatic effects as leukaemia and cancer is a process comparable to that of induction by radiation of genetic mutations . . . this view tends to tinge the interpretation of subsequent data." The statement emphasizes that it is not possible at the present time to decide whether there is or is not a threshold dose concerned in the induction of leukaemia and cancer, "and the only scientific attitude to the problem at present is one of suspended judgment."

On that part of the U.N. report concerned with the somatic effects of radiation the M.R.C. statement indicates only relatively minor differences in points of view. The M.R.C. committee was, for instance, surprised to learn from the report that a temporary drop in the level of white blood cells had been observed after a single dose of radiation as small as 250 mr—in the opinion of the committee doses at least 50 to 100 times larger were required to produce unequi-

vocal effects. The committee also thought that the sentence, "Malformation and other pathological conditions have been observed following exposure of pregnant women to accidental and therapeutic irradiation and to diagnostic procedures, e.g., pelvimetry," was unduly alarming—no evidence being available that the doses of radiation used in diagnostic procedures have produced congenital malformation in the child.

The M.R.C. committee is now prepared to agree with the American estimate that the genetically significant dose from diagnostic radiology may be as much as 100% of the natural background radiation in countries with extensive medical facilities.

In accepting the estimate of the U.N. report that over a period of 30 years the genetically significant dose to the reproductive organs from radiation resulting from weapon tests could be 0.06 rem or 0.12 rem (depending which of two assumptions regarding the scale of future tests was chosen), the M.R.C. statement points out that these estimates should be considered against the dose of 3 rem which would, on the average, be received from the natural background radiation over the same period.

The M.R.C. committee agrees with the conclusion of the U.N. report that the average concentration of strontium-90 in the bones of those living on a "plant-type" diet may be up to 5 to 6 times that in the bones of those on a "milk-type" diet. Elaborating this, the committee explains that the cow is, as it were, interposed as a partial filter between vegetation, which is contaminated with strontium-90, and the human body. In countries where, for instance, rice is the staple food there is no such filter.

Concluding the statement, the M.R.C. committee emphasizes that it was in no disagreement with the U.N. report on any major piece of information or concept.

New Appliances

AN ADJUSTABLE BED

Dr. A. C. E. BREACH writes: An engineer and I, a retired medical practitioner, set ourselves the task of designing at moderate cost a piece of equipment which would relieve much of the discomfort associated with long confinement to bed. We have sought to satisfy four requirements which we regard as essential: (1) a back support sloping at the right angle; (2) a support for the buttocks and thighs, so inclined as to counteract the tendency to slip down and to transfer the downward thrust of the body from the sacrum to the buttocks; (3) a support for the legs and feet, inclined so as to allow the knees to be comfortably bent and the weight of the legs to be spread over the largest surface possible rather than concentrated upon the heels; and (4) means whereby the patient on his own initiative and without assistance can vary his position at will.

A specially designed bedstead of drawn-steel tube is mounted upon standard castors. Upon this is pivotally supported the adjustable bed consisting of three rectangular frames—the "back frame," the "seat frame," and the "leg

frame"; these frames are hinged one to another. In the rest position they are aligned parallel with the floor as an ordinary bed. They are covered with a suitable material to give a flat surface, upon which rests a standard "flocupillo"-type mattress (6 ft. by 3 ft. by 4 in. (180 by 90 by 10 cm.)). This mattress may itself be sectioned, but in practice this seems to be unnecessary.

The frames are connected beneath the bed by a series of paired link-rods, so arranged that an interrelated harmonic movement is secured between the three frames. Thus, upward tilting of the back frame results in a progressive downward movement of the adjacent end of the seat frame, whilst at the same time the foot end of the leg frame swings downward about its pivotal axis. It will be seen from the line drawings that this movement may be continued to the point at which the patient is sitting upright with his feet ready to step off on to the floor. Strong detachable handgrips are provided to help him in and out of the bed (they also serve as a rest for a bed-table), and the bedstead has been so designed that there is no foot-bar to obstruct the patient as he walks away.

Provision is also made to enable the nurse to fix the leg frame in the horizontal position, while leaving the back and seat frames free to move in harmony.

Two models have been designed. In model A (illustrated) movement is effected by a

small electric motor mounted on the bedstead. Two push-buttons are provided for the patient's use in any convenient position. One raises the back, the other lowers it; movement ceases when the button is released. Model B has been designed for cases where an electric supply is not available or where it is thought desirable for therapeutic reasons that the patient should take active measures for his own comfort. Movement is effected by means of a small hand-pump operating a hydraulic ram mounted on the bedstead.

In addition to promoting the general comfort of the patient, the inventors consider that this apparatus provides the following specific advantages: (a) The orthopaedic patient can adjust his position, day or night, to give maximum comfort and can vary it at will. (b) The tendency to pressure sores should be much reduced. (c) Convalescence should be accelerated by early movement, greater comfort, and the inspiration of independent action. (d) Where necessary, change of position of the anaesthetized, unconscious, or helpless patient may be effected without manual lifting by one nurse by finger pressure. (e) The out manual lifting by one nurse by finger pressure. (e) The load on the nursing staff should be much reduced, since

(Continued at foot of next column)

To-day's Drugs

In this column we publish from time to time authoritative notes on a selection of drugs in current use.

Nilergex (Imperial Chemical Industries Ltd.).—Nilergex, or isothipendyl, is another antihistamine drug. Its chemical structure, 10-(2-dimethylaminopropyl)-9-thia-1:10-diazanthracene, resembles that of promethazine, but with a second nitrogen atom introduced into the phenothiazine nucleus. But, whereas promethazine is strongly sedative and long-acting, nilergex is reported to cause less drowsiness than any other antihistamine drug—for example, in only 5 out of 602 patients in an American trial. However, direct clinical comparison with other drugs has not been made. It has a relatively short action, and when administered orally in 4-mg. tablets or as a syrup it must be given 3 or 4 times a day. Tablets containing 12 mg., with a specially coated inner core, are intended to give sustained action for 12 hours.

N.H.S. basic price: 100 4-mg. tabs., 33s. 4d.; 100 12-mg. tabs., 18s. 4d.; syrup, 500 ml., 11s. 8d.

Triostam (Burroughs Wellcome and Co.).—Sodium antimonyl gluconate, as amorphous white powder, standardized to contain 36% of trivalent antimony. The principal advantage of this trivalent antimonyl compound over sodium antimonyl tartrate in the treatment of schistosomiasis is that its toxicity is low. The nausea and vomiting so common in patients receiving sodium antimonyl tartrate very seldom occur in those receiving triostam, but unfortunately the relapse rate following full courses of the latter is very much higher than that following courses of sodium antimonyl tartrate, and, like it, it must be administered intravenously. It is not therefore the drug of choice if the aim is to eradicate infection entirely, for which purpose there is nothing superior to sodium antimonyl tartrate. Unfortunately, however, treatment with sodium antimonyl tartrate necessitates admission to hospital and close medical supervision. There is thus a place for triostam for controlling symptoms and for reducing the worm load in communities in the tropics where treatment on an out-patient basis only is practicable.

N.H.S. basic price: 6 ampoules, 6s. 7d.

Entobex (Ciba Laboratories Ltd.).—4:7-Phenanthroline 5:6-quinone (Compound 11925C) in tablets of 50 mg. This drug has only very recently been placed on the market and very few results of clinical trials with it have been published. The manufacturers, however, report that *in vitro* it has amoebicidal action at a dilution of 1 in 16,000 and is also effective against various bacteria, including *Staphylococcus aureus*, *Streptococcus faecalis*, *Escherichia coli*, and *Salmonella typhi*. It appears to be relatively free from toxic effect in animals, 100 mg. per kilogram having been given to rat daily for 21 days, following which histological examination of the internal organs revealed no abnormalities. In man also side-effects have so far been limited to nausea and vomiting.

Until further experience with this amoebicide is obtained it is doubtful whether it is wise to use it for routine purposes, but it is of interest as an experimental therapeutic substance.

N.H.S. basic price: 100 tabs., 39s.

(Continued from preceding column)

even the heaviest patient can be adjusted in position with lifting. (f) The aged are encouraged to retain a measure of independence. (g) A number of special medical and surgical needs have been anticipated in the design. (h) Nursing of the sick and the aged in their own homes should be made easier, especially if beds of this type could be made available on loan or hire.

[This adjustable bed is marketed by Egerton Engineering, 1, Walters Yard, Bromley, Kent.]

area. It has been requested that this card, with relevant details added, should accompany any patient sent up for admission who is known to have been treated with steroids, chlorpromazine, or any other drugs the general practitioner considers should be made known to the hospital consultant. One case escaped this net. A very ill patient with ulcerative colitis, under treatment in one department of this hospital, perforated, and was transferred to another department for operation that night. She died, without recovering consciousness, of a fulminating peritonitis. Three explanations of this case are possible. (1) The case was hopeless from the start—most probable. (2) Insufficient cortisone was given during operation. (3) The patient was "cortisone sensitive," as has been described in certain kinds of experimental animals where the mildest infections rapidly become overwhelming if the animal is undergoing steroid therapy. So far it is believed that man does not normally belong to this group, but of course our knowledge of the long-term effects of steroid therapy is still in its infancy.—I am, etc.,

H. E. POOLER.

Sweet Tooth and Decay

SIR,—Your leading article (*Journal*, August 2, p. 293) so admirably stresses the most important factors in the causation of dental caries that I only diffidently criticize it. You imply, perhaps unintentionally, that erosion caused by acid drinks is often a predisposing factor, but this is not orthodox teaching. On the contrary, such acids stimulate salivation and may therefore have a protective effect, and erosion rarely occurs at the contact points or in the occlusal pits, where most caries begins, and is not nearly so common as caries is on the buccal surfaces.

To condemn round-the-clock eating of all carbohydrate foods is too sweeping. Untreated vegetables and fruit, except bananas, can be exonerated, and there is little evidence against rice, macaroni, or cooked whole vegetables. Chewing-gum, like sugar cane and other fibrous foods, may even be beneficial, and sorbital is a sweet carbohydrate that does not readily ferment; sweets made from it are advertised in the *Journal of the American Dental Association* and sold with the claim "safe for teeth." The foods to be condemned are those which leave deposits of concentrated starch or sugars, or sugars in solution, stagnating in the mouth after eating.

Confectionery frequently consumed is likely to remain popular despite all educational effort. Is it necessary, however, that it should lack such qualities of texture, consistency, and content of roughage and water as render other fermentable carbohydrate foods not only wholesome but also succulent? Is it not conceivable that "texturization" of confectionery could restore the originally natural conformity between what tastes good and what is good for us? Such an invention to make popular food more wholesome, together with fluoridation to do the same to water, might bring caries immunity to the masses whose appetites triumph over prudence.—I am, etc.,

London, S.W.10.

R. B. D. STOCKER.

Depressive States

SIR,—Dr. Gerald Garmany's contribution on the above subject (*Journal*, August 9, p. 341) is of considerable interest, and especially his conclusion that "the distinction between these three forms of depression [endogenous, reactive, and involuntal] and particularly between the reactive and endogenous varieties, is an unreal one." With this latter conclusion of Dr. Garmany's I am in whole-hearted agreement, and I am also in agreement with his further conclusion that "constitutional predisposition and the incidence of stress factors appears to be much the same in these groups." But, in view of the above findings, it is not easy to understand Dr. Garmany's apparent reluctance to give

E.C.T. in what he earlier called "reactive depression," but which he later states means only a "mild" depression.

In my experience, the most "mild" depression, perhaps expressed only by a little tearfulness and beginning disturbed sleep, reacts as promptly to E.C.T. as the most severe depression, but usually much fewer E.C.T.s are required. If one withholds E.C.T. from these cases, what can one give? Sedatives and reassurance? Some years ago that was all one could give, and not infrequently one found that it did not work, or, if it did, only with great tediousness and distress to the patient and his family—and not inconsiderable stress to the psychiatrist. (On clinical grounds alone it is almost impossible, in my opinion, to eliminate the risk of suicide in even the most apparently "mild" depression.) If such cases are reluctant to come into hospital for the necessary one to three weeks' treatment, E.C.T. can be given in the out-patient department. In such cases I usually asked the patient to report fasting at 9 a.m., and to remain in the hospital for lunch. One can then make sure that they do not suffer from any significant confusion or amnesia before allowing them to travel home.

Dr. Garmany dislikes leucotomy, but I am sure he will admit that there is a place for it when all other measures have obviously failed. In the latter category I would include a prolonged course of insulin coma therapy, which, in my experience, may have a profoundly beneficial effect in recurrent and resistant manic-depressive conditions, and also in some paranoid conditions. For "anxiety states" (by which I presume Dr. Garmany means uncomplicated "anxiety hysteria"), Dr. Garmany rightly withholds E.C.T., which in any case would be quite valueless. But he does not mention suggestion, to which, if the diagnosis is correct, these patients should immediately respond.—I am, etc.,

Pinner.

ROBERT THOMPSON.

Childhood Malignancies

SIR,—I have read with great interest the paper by Dr. Alice Stewart and her colleagues on a survey of childhood malignancies (*Journal*, June 28, p. 1495). If one believes rightly that myelocytes in leukaemia grow locally from the reticuloendothelial apparatus and other connective tissues, the whole question is reduced to the problem of malignant changes induced by local radiation of x rays, either for diagnostic or therapeutic purposes, everywhere in the body. It is unnecessary to assume that the bone marrow must be irradiated in leukaemia, which would need a bigger dose to penetrate the bone than is used in diagnostic radiology as a rule.—I am, etc.,

Cordoba, Argentine.

P. BUSSE GRAWITZ.

Halothane Concentration

SIR,—There appears to be an attempt to defend what must surely be a retrograde step—namely, the use of a Rowbotham bottle in a circle absorption system. I have shown (*Journal*, May 17, p. 1180) that this practice trebles the resistance in a circle system to a figure of 13 mm. Hg using an 80-litres-per-minute gas flow. It should be borne in mind that in the event of coughing or straining gas flows of up to 600 litres per minute may occur. Dr. Herbert C. Newman (*Journal*, June 14, p. 1417) estimates that the work of breathing is increased by 15% by the bottle, after assuming that respiratory patterns are similar in anaesthetized and conscious subjects. It is generally held that inspiration is shortened during surgical anaesthesia, so that an increase of 30% might perhaps be a more appropriate estimate.

The quiet breathing that usually occurs during halothane anaesthesia is used as an excuse for the practice, but this has its own dangers. Dr. F. R. Gusterson (*Journal*, June 7, p. 1356) quotes a patient with a minute volume of 3,600 c.c., a low figure even by the endotracheal route, suggesting respiratory acidosis. Some absorption systems do not function efficiently at such low volumes. I reproduced the

conditions described using a Coxeter-Mushin Mk. I unit, fresh soda-lime, and spirometric control. The inhaled mixture analysed by the B.O.C. analyser contained 2% carbon dioxide.

There is only one thing to be said in favour of this use of the Rowbotham bottle, and that is that it is virtually incapable of delivering a lethal concentration of halothane vapour; otherwise the larger bottle mentioned by Dr. C. G. Blakeley (*Journal*, July 26, p. 249) would clearly be more suitable. If, however, the anaesthetist is content to use an unknown concentration of the vapour, almost the same conditions as those supplied by the Rowbotham bottle can be achieved by placing 20 c.c. halothane in the standard ether vaporizer on a circle system, having first unscrewed and removed the copper baffle. But halothane tends to ruin the apparatus.

At this stage in the evolution of halothane anaesthesia I suggest that what is required is an economical method of using the drug, but with a check on the concentration used. I have been using such a method for some time now with satisfactory results. By a simple modification of the standard "trilene" bottle a known concentration of halothane is delivered with nitrous oxide and oxygen at a fresh gas flow of 1-2 litres per minute into an absorption system. Employing halothane in a concentration of 2%, the consumption is about 10 c.c. per hour, at a cost of around 10s. I will offer this for publication shortly.—I am, etc.,

Chislehurst.

JOHN BULLOUGH.

Anorexia Nervosa

SIR,—I read with interest Dr. E. Williams's remarks (*Journal*, July 26, p. 190) on the treatment of anorexia nervosa by intubation. In this unit we have given protein-fortified milk feeds by intragastric drip, the patient receiving 2,000-3,000 calories daily. Even with this method the patient requires constant supervision; the drip may be disconnected and milk poured down the sink or else vomited. This behaviour is if the patient is allowed up to toilet. This behaviour is the central issue in anorexia nervosa: food to such patients is intolerable, and to avoid eating every conceivable device is used—even to the death. I know of one patient who when admitted in *extremis* whispered, "You won't make me eat, doctor, will you." It is this repugnance for food which has led many investigators to see a psychological aetiology upon which specific treatment could be based. Other psychological factors have to be taken into account. It is possible for the nursing staff to become demoralized in the presence of these patients, who evoke considerable anxiety and hostility by their refusal to eat. Attitudes initially therapeutic eventually become punitive. The detriment of the patient's condition, unless the physician is prepared to discuss each individual case with the nursing staff and give all possible support.—I am, etc.,

Manchester, 13..

LINTON GRIMSHAW.

SIR,—In his article on anorexia nervosa (*Journal*, July 26, p. 190), Dr. Eirian Williams appears to imply two important opinions although he never makes either of them explicit. (1) anorexia nervosa is a somatic disorder, with no important psychological aspects; (2) tube-feeding is not merely symptomatic treatment, but is also curative. These opinions are at variance with current views on the subject and require strong proof.

Certain points should be noted in regard to Dr. Williams's material. (1) The follow-up periods of the treated and untreated groups are not comparable, and in the treated group two patients (cases 52 and 53) have had hardly any follow-up. The average follow-up period for the untreated group was almost four times that of the treated group. (2) The seven untraced patients, and the patient whose relatives

refused to give information, should be omitted, but Dr. Williams seems inclined to regard them as non-recoveries in the untreated group. (3) It is not clear that he uses the same criteria for recovery in the treated as in the untreated group, for he classifies as "well" a 15-year-old schoolgirl who is truanting from school, but not case 38, who is symptom-free and has regular periods, but is "undernourished." This handling of the material causes a bias in favour of the treated group.

Even if no correction is made for this bias, Dr. Williams's figures are as follows. *Recovery*.—"Treated" Patients: "Well," 6; "Not Well," 1. "Untreated" Patients: "Well," 19; "Not Well," 27. $\chi^2=3.2$ (using Yates's correction for continuity). This value fails to reach significance at the 0.05 level of probability. *Mortality*.—"Treated" Patients: Alive, 6; Dead, 1. "Untreated" Patients: Alive, 37; Dead, 9. These figures are very little different from random expectation. Dr. Williams has therefore failed to prove that tube-feeding benefited his patients in the long run.—I am, etc.,

Dundee.

JAMES H. BROWN.

SIR,—In the article "Anorexia Nervosa: A Somatic Disorder" (*Journal*, July 26, p. 190), Dr. E. Williams has expressed some views and made certain points which need comment. The author calls anorexia nervosa primarily a wasting disease and a somatic disorder. He produces no valid evidence for this, and, moreover, the fact that the patient deliberately avoids eating and actively resists feeding casts grave doubts on the author's suggestions. He says that confusion in treatment of this disorder is due to the mystery surrounding its aetiology, which was at one time explained in superficial but understandable terms. I do not believe there is any mystery about its aetiology—indeed, there is confusion about it, and this is a sad reflection of our ignorance about the illness. But, while awareness of one's ignorance can be heuristically stimulating, acceptance of superficial and unfounded, though easily understandable, explanations may have the reverse effect.

The author is right in drawing attention to the urgency of treatment and the dangers of marked wasting leading to death. Although intubation has been successful, it is clear that fair success has also been achieved in patients who did not receive this treatment. Lately rauwolfia alkaloids (reserpine) appear to have proved promising in dealing with not eating and weight loss. They deserve a trial even though they have no deterrent value. Speaking of treatment by psychiatrists, the author says, "Psychiatrists almost without exception consider psychotherapy the appropriate treatment." I do not know on what experience or authority this statement is based, which is in any case not in accordance with facts. The author discusses the works by Kay and Leigh,¹ who do not think psychotherapy the suitable treatment. Use of rauwolfia alkaloids for anorexia is another example. This, however, does not mean to imply that psychotherapy is invalid.

Lastly, the author appears disturbed that the treatment of this disorder has strayed into the realms of psychiatry, and he is trying to make a case against this situation. Among the causes he gives for this straying are the discouraging results of treatment based on general medicine principles, and the tendency of anorexia nervosa sometimes to simulate psychoses. As for the former, I do not know how the principles of treatment in psychiatry differ from the principles of general medicine—I should have thought that they were the same. Secondly, simulation of psychoses in anorexia nervosa is only occasional.

In conclusion this appeal seems not only unwarranted but a dangerous one, because it reflects a thinking aimed at artificial division of illness into somatic and psychological. The overlapping influence of somatic, psychological, and environmental factors in the causation of cures of disease is so vast and varied that any approach short of a multi-dimensional one is not only likely to be of disadvantage to the patient but dangerous to one's own thinking.—I am, etc.,

Coulson, Surrey.

N. H. RATHOD.

Apathy About Public Health

SIR,—In an annotation on shoe-fitting fluoroscopes (*Journal*, June 14, p. 1404) certain Home Office requirements for their continued use were quoted. It implies that old, possibly dangerous, machines may be used for yet another five years, until July 1, 1963. To have a shoe-fitting fluoroscope or not has been discussed already.^{1,2,3} The important fact remains that Dr. E. D. Dyson² carried out his observations on well-constructed, adequately screened machines, but what of others? These can carry on apparently for the next five years. And no doubt they will be used by many customers.

I have recently attended a course of social medicine from which it would appear that official and public apathy occurs all too frequently. The Children Act of 1908, para. 15, requires the use of fireguards on open fire grates where there are children under the age of 7. However, to fix guards on electric, gas, and oil fires was not made law until the 1953 Heating Appliances (Fireguards) Act.

A Royal Commission on Tuberculosis, sitting in 1901–11, published interim reports in 1904 and 1907 from which it became clear that human and bovine tubercle bacilli were morphologically the same. In 1909 an appendix was issued describing the risk of human infection via the milk of a tuberculous cow. This was confirmed in the Commission's final report published in 1911. Further recommendations were made suggesting the prohibition of tuberculous persons in dairies.

The General Powers Act, 1907, had given the L.C.C. the right to examine the milk supplies for London. In a report of the M.O.H. to the L.C.C. for 1909, quoted in *The Times* of July 13, 1911, it was stated that 10.4% of random milk samples proved to be tuberculous. Although the supply of diseased milk could be stopped going to London there was no law to prevent the tuberculous cows being disposed of to another owner.

By 1911 there was abundant evidence of the danger of tuberculous milk. And in 1914 the Milk and Dairies Act was passed. This prohibited both the sale of milk from tuberculous cows and the employment of tuberculous persons in dairies. It was to be put into effect in 1915. The Milk and Dairies (Consolidation) Act of 1915 consolidated various enactments relating to milk and dairies, and as a result of the Great War, 1914–19, the Milk and Dairies (Postponement) Act, 1915, was passed, stating that the Act should be put into effect not later than one year after the end of the war. Yet in 1922 further legislation, the Milk and Dairies (Amendment) Act, postponed it until 1925, which was fourteen years after the final report of the 1901–11 Royal Commission.—I am, etc.,

Edinburgh.

Electrified

SIR,—The experience described by Mr. L. H. Pimm (*Journal*, August 9, p. 390) is familiar to me. In the performance of hundreds of formal medical examinations a year I have come to expect it to occur perhaps once in three months and in the manner described, except that in my case the gap bridged by the spark is so small as to give the impression that it coincides with touch. Being unable to explain the phenomenon, it is my custom to ignore it when it occurs, but once, when the contact was finger to chin, the patient observed, "Good heavens, was that you?" And on another, quite recent, occasion the spark discharged from my finger-tip to the patient's bare shoulder, causing him to jump. On asking him why he had jumped he replied that "something pricked me." These reassurances confirmed the reality of the sensory and auditory impressions I had received.—I am, etc.,

Deal.

W. B. ROANTREE.

Prednisone and Nasal Allergic Disease

SIR,—Since a previous letter by one of us (H. J. S.) was published in the *Journal* of February 16, 1957 (p. 398), on the use of oral "prednisone" in the treatment of chronic nasal allergy and polyposis, planned courses of treatment have been completed in a further 28 adults who could all be said to be allergic veterans. The drug was given in tablet form, a typical course being 5 mg. three times daily for 1–2 weeks and then a minimum maintenance dose for a variable period. The length of treatment varied from 3 to 12 weeks, the average being 8 weeks. In many patients the maintenance dose was found to be only 5 or 2.5 mg. daily. Side effects were mild and occurred in only two patients. One developed an erythematous rash on the face accompanied by frequency of micturition and some abdominal distension. The other patient was temporarily nauseated, but without other symptoms or signs.

The average duration of follow-up after completion of treatment has ranged from 3 to 8 months. Out of the 28 patients treated, 22 showed marked subjective and objective relief during treatment; and of these, 14 have relapsed after variable periods, leaving eight patients in whom relief has so far persisted. It is felt that, despite a high rate of relapse, the rapid response to small doses of oral "prednisone" by the majority of patients with severe nasal allergy justifies its use in selected cases. A full report is to be published in the *Journal of Laryngology and Otology*.—We are, etc.,

Human Factor in Diagnosis

SIR,—Dr. C. P. E. Elliott-Binns is to be congratulated upon his excellent article on the human factor as a cause of delay in diagnosis in general practice (*Journal*, August 2, p. 271). Since the patients he describes are presumably his own, he is to be particularly congratulated upon his fearless honesty in describing them so clearly. There are several observations I would like to make in an endeavour to orientate the article still more clearly. Non-general practitioners should not assume that the good general practitioner may be evaluated by the alacrity with which he diagnoses disease causing structural change. Although it is to be hoped that he will recognize these diseases at the earliest opportunity, it is necessary to remember that the family doctor has continued care of the whole person—not specific care for a physical disease. The human factor, which Dr. Elliott-Binns points out is important, is of such supreme significance in general practice that it is essential that a good general practitioner shall have become conscious of it and shall have attempted to adapt himself to it.

May I suggest that three principles to follow are: (1) Never to "dabble" with patients or illness. If the doctor is confronted with an apparently trivial illness in irritating circumstances (and this is a common experience), such as Case 2 in the article, a safety system should automatically be put into operation. This may be to take a deep breath, re-enter the house, sit down, pause, and examine the affected part carefully: alternatively, it may be to arrange to see it at the next visit (and to place the onus for remembering upon the patient). In general, time is saved and irritation avoided by giving thorough attention to the aspect of the patient rather than superficial attention to much of him. For example, a careful history alone may be superior to a casual one incorporating shoddy examination. Similarly, thorough examination of the chest alone may be superior to casual examination of the whole patient. (2) To exercise special caution with friends, relatives, social contacts, and "untouchables." If the doctor finds that the human factor causes him embarrassment or impairs his efficiency in attending such people, he should make special efforts to overcompensate his natural reaction, or alternatively refuse, with necessary explanation, to attend them. (I know a hospital sister whose carcinoma of rectum was diagnosed late because her attendant was reluctant to make a rectal examination.) (3) To attempt to synthesize in each patient the personal relationship to him (which is essential) with the impersonal detached understanding of him.

AUG. 23, 1958

CORRESPONDENCE

BRITISH
MEDICAL JOURNAL 513

Obituary

H. A. SANDIFORD, M.C., M.B., D.P.H.

Brigadier H. A. Sandiford, who died suddenly at his home at Windsor on August 13, aged 66, was the first medical director of the Commonwealth Medical Advisory Bureau and of the International Medical Advisory Bureau of the B.M.A. He retired from this appointment at the end of last year on reaching the age limit. Before joining the staff of the B.M.A. he had had a distinguished career as a regular officer in the R.A.M.C., culminating in his appointment as the first Director of Army Psychiatry at the War Office. At B.M.A. House he quickly established himself in the affections of his colleagues, and, being the fortunate possessor of an outstandingly genial personality, he added to his many friends through his efforts on behalf of the overseas visitors who consulted him at the Bureau.

Hugh Arthur Sandiford was born at Manchester on May 26, 1892, and was educated at Manchester Grammar School and at the University of Manchester, where he graduated M.B., Ch.B. in December, 1914. In the following month he entered the R.A.M.C. for service in the first world war. He was awarded the Military Cross in 1917 in circumstances officially described as follows: "He took up a position immediately behind the front line during an attack and dressed the wounded in the open. He displayed great coolness and gallantry under heavy artillery fire, working in an exposed position for forty-eight hours." Sandiford decided to make the Army his career, and for fifteen years or so was employed in all branches of clinical medicine and in general medical administration. He took the Cambridge D.P.H. in 1925, and as a hygiene specialist he was, from 1933, successively instructor at the Army School of Hygiene, Deputy Assistant Director of Hygiene at Peshawar, Assistant Director of Hygiene at the War Office, and Deputy Director of Hygiene in the Eastern Command. In the assessment of physical fitness he had a wide experience, and he was one of the first to grasp the importance of devising efficient methods of selection. His last military appointment gave him an opportunity to display his ability in this respect. The second world war had run half its course when, in 1942, he was invited to assume the post of Director of Army Psychiatry at the War Office. In his case it was more than just filling an appointment: he had to create the whole structure of which he had been nominated as the first director. In this complex and difficult task he was highly successful. Although not trained to be a psychiatrist, he had acquired in the course of his career a good knowledge of psychiatry and its social applications.

An extremely hard worker, very painstaking over detail, he never lost sight of the wood for trees. As Director of Army Psychiatry he had to establish liaison with the Emergency Medical Service, the Board of Control, and the medical superintendents of civil hospitals, and during his period at the War Office from 1938 to 1946, when he retired from the Army, he worked in close contact with many of the senior medical officers of the Dominions and Allied medical services. He had a very keen mind and was a shrewd judge of character, but his kindly manner and

Lastly, I think that Dr. Elliott-Binns, in trying to establish his case, has been unnecessarily hard upon himself, and in some of the cases he describes the disease was doubtfully possible of diagnosis earlier: in one, the hospital doctors also had difficulty. I think those of us who can see (and we are growing in numbers daily) the extreme importance of the human factor in general practice should labour to avoid overstatement of our views. We should attempt to integrate this factor into the accepted framework of the medicine we were taught to practise in hospital. Dr. Elliott-Binns has shown clearly that our problem as family doctors is the synthesis of these two strong and sometimes conflicting forces. It is only by writing about them, clarifying and discussing them, that the synthesis will be achieved, and to the great benefit of our patients.—I am, etc.,

M. H. S. BOUND.

St. Peter Port, Guernsey.

Psoriasis of the Mouth

SIR,—Dr. W. W. Gunther, of Newcastle, Australia (*Journal*, August 2, p. 327), asks if it is not possible that some cases of lichen planus of the mouth could have been psoriasis. Psoriasis of the mouth, although not very common, is also not very rare. At the Royal Dental Hospital mon, is also not very rare. The oral of London we see quite a number of these cases. The oral lesions more often than not attack the upper surface of the tongue and look very much the same as the lesions of the skin—i.e., the central scale with the surrounding reddened ring spreading outwards—and usually occur in conjunction with the general skin condition. Lesions also occur on the buccal mucosa and are not quite so typical, making it possible to mistake them for lichen planus. It is my experience that some form of irritation—jagged tooth or ill-fitting denture—originates the condition. These cases are treated in the electrotherapy department by means of concentrated actinic rays (the titanium arc lamp) with most satisfactory results.—I am, etc.,

London, W.1.

ROBERT LEAVER.

Coudé Catheter

SIR,—In volume 6 of the winter number of *The Leech*—the journal of the Cardiff Medical Students' Club—there appeared an article on Emile Coudé, 1800–70, a surgeon of Niort, France, who, it was alleged, invented, and in 1835 published an account of, the coudé catheter. This biography was written in a serious and restrained vein, and was replete with two references, one to the autobiography of Emile Coudé, and another to *Le Mois Medical* for a description of the invention. In addition, the article contained a reproduction of a woodcut purporting to be a likeness of the inventor.

We have been able to prove that the whole of this article is a fabrication, and the references are fictitious. To expose this deception is of practical importance. As a result of this hoax, a number of pages of the 11th edition of *A Short Practice of Surgery* that were passed for press have had to be reset in as far as the capital "C" of Coudé is concerned, and biographical footnotes to Emile Coudé deleted. To save others from falling into this mire, we hope that you will publish this letter. The coudé catheter was invented by Louis Mercier, 1811–82, the eminent Paris urologist, so well known for his description of the coudé ureteric bar. Mercier announced the invention of the coudé catheter in 1836 and of the bi-coudé catheter in 1841. Being translated, *coudé* (the adjective) means bent; *coudé* (the noun) means elbow.—We are, etc.,

HAMILTON BAILEY.

W. J. BISHOP.

Editor, *Medical History*.

A. CLIFFORD MORSON,

President, *Société Internationale d'Urologie*.

Sholden, Kent.

friendly nature made him the most approachable of men. He was respected and liked by all who worked under him, as well as by those who worked with him. In 1933 he was appointed an officer of the Venerable Order of St. John of Jerusalem, and a few months before he retired from the Army he was appointed an Honorary Physician to the King.

In 1947 the British Medical Association decided to establish an Empire (now Commonwealth) Medical Advisory Bureau to assist members of the profession coming to Great Britain from the Dominions and Colonies for postgraduate study and other purposes. Out of well over 100 applicants for the post of medical director of the new bureau, Sandiford was selected. With so many applications to consider, the work of the Staffing Committee was by no means easy; but subsequent events proved its choice to have been an exceptionally wise one. Once again Sandiford was asked to start from scratch and to create a department, and once again he proved to be the man for the task. With his splendid gifts for organization and enviable capacity for getting on well with all sorts and conditions of men, he took the work of establishing the Empire Medical Advisory Bureau in his stride, and soon developed a service which as time went on became of increasing value—a service which included advice on postgraduate courses and diplomas, examinations, hospital appointments, part-time employment, visits to hospitals and clinics, medical registration, and accommodation. His help in connexion with accommodation was of particular value, especially during the early years of the Bureau's existence, when the housing problem in the United Kingdom was most acute. The pamphlet he prepared containing a summary of the regulations for diplomas and courses of instruction in postgraduate medicine obtainable in the United Kingdom was a most useful one and is much used by the deans of medical schools in the Commonwealth and elsewhere. His help and advice to correspondents and those who visited his office will be remembered by many with real gratitude.

Sandy's friendliness and good nature shone like a bright light over the Bureau's "At Homes" to overseas visitors. At these functions, as in his career in general, his wife gave him most valuable and devoted support. They had three children, and their family life was of the happiest. Their son, Dr. R. H. Sandiford, is in practice in Newport in the Isle of Wight, and one of their two daughters, herself a trained psychologist, is married to Dr. T. Grygier, head of the department of clinical psychology and research at Banstead Hospital.

Mr. A. M. A. MOORE, chairman of the Commonwealth Medical Advisory Bureau, writes: The sudden death of Brigadier H. A. Sandiford so soon after his retirement has brought great sorrow to a host of friends throughout the British Commonwealth. With his passing the medical profession is deprived of a very distinguished member, and many doctors have lost a loyal and good friend. Ten years ago, after a distinguished career in the R.A.M.C., he was chosen from over 100 applicants for the post of director of the newly formed Empire Medical Advisory Bureau. During the presidency of Sir Hugh Lett the Council of the Association decided to establish an advisory bureau to assist members of the medical profession coming to this country from the British Commonwealth for postgraduate studies, and it was left to Brigadier Sandiford to build up this new department. His Army experience of organization was to prove of the greatest value in this work, and in a very short period he succeeded in building up the framework of the bureau as we know it to-day. He was a delightful colleague with whom to work, and the members of his staff came to regard him with the greatest affection. His work brought him into the closest contact with Sir Hugh Lett and with Mr. L. R. Broster, who were the first two chairmen of his management committee, and he spent much of his time developing friendly contacts with the leaders of the medical profession and with the universities in this country. In addition, he developed the International Medical Advisory Bureau, which provides a useful service

for doctors from other countries. At the time of the Hungarian tragedy Brigadier Sandiford was given the responsibility of organizing the relief service provided by the B.M.A. for the many refugee Hungarian doctors who came to Britain. He also served on the Lord Mayor's committee dealing with this problem and developed the keenest personal interest in these unfortunate doctors, whom he was able to help in a great many ways. In all his work for the Bureaux, which has brought so much good will to this country from members of the medical profession abroad, Sandy was loyally assisted by his very charming wife, known to so many friends as Prue, and our heartfelt sympathy goes out to her in the tragic loss she has sustained. In the Bureaux Sandy has left a monument by which he will always be remembered.

Dr. D. P. STEVENSON, Deputy Secretary of the B.M.A., writes: The news of Brigadier Sandiford's death so soon after his retirement from the Headquarters staff of the Association has come as a very sad blow to his many friends at B.M.A. House. Sandy—as he was known to us all—joined the Headquarters staff in March, 1948, as the first director of the Empire (now Commonwealth) Medical Advisory Bureau, and immediately set about his new task with characteristic drive and enthusiasm. The annual reports that he made on the work of the Bureau are themselves evidence of how this new venture of the Association has helped to cement friendship between doctors in this country and those overseas, and its success was largely due to Sandiford's outstanding personality and leadership. At Headquarters Sandy will always be remembered as a friendly colleague whose charm, cheerfulness, and enthusiasm for the work he was doing were an inspiration to us all. It is tragic that after such devoted service to his profession his retirement should be cut so short, and we extend our deepest sympathy to his widow, his son, and his two daughters.

G. R. H. writes: It is no secret that in the last war senior regular Army medical officers did not always inspire affection and respect among civilian specialists serving in the R.A.M.C. under their direction. It is not surprising, therefore, that when Sandiford was appointed as the first Director of Army Psychiatry many psychiatrists were critical of the choice of a regular officer without specialist experience for the job. But those of us who had the opportunity of working closely with him realized rapidly how wise Sir Alexander Hood's choice had been. In leaving an Assistant Directorship of Army Hygiene to become the first Director of Army Psychiatry Sandiford gave up a career that would have taken him to the top of his specialty, but what his own specialty lost Army psychiatry gained. He was not only a good "public health man" but a wise and shrewd administrator of a clinical service who set out to give the clinician the opportunity to do good work. More than that, working with him was for many of us the first close contact we had had with the practitioner of preventive medicine. It had a lasting effect on the viewpoint of many of us, and was one of the important influences which contributed to the growth of interest in recent times in the social and preventive aspects of psychiatry, although he was much too modest to have realized it. He was a calm, gentle, friendly man, who remained unruffled by crises, yet was capable when necessary of a firmness and determination which one might not have suspected until one had provoked it. I am sure that all who worked closely with him in the early days of Army psychiatry will think of him, as I do, with admiration and affection.

Mr. D. C. BOWIE writes: It is sad that Brigadier Sandiford was not spared longer to enjoy the period of retirement in his new house to which he had looked forward and which he would have enjoyed so much. It was after the war that I found him installed as Medical Director of the British Medical Association's Empire (later Commonwealth) Medical Advisory Bureau. The Bureau had many facets to its activities and very many overseas medical men and women

have had cause to be grateful to the organization he built up so painstakingly for help and information of all types, but it was in the field of postgraduate medical education that I came into formal contact with him. The details of our numerous consultations do not matter, but the fact that he established a co-operative relationship with an academic body such as the British Postgraduate Medical Federation as he did with other university bodies in the United Kingdom showed that he was alive to academic values as well as to the day-to-day needs of his medical visitors. In turn, he had a store of information and knowledge of people all over the country which were most valuable to medical visitors who wanted to see something of medical practice of all kinds during a holiday visit to this country and whom we were able to refer to his capable hands. I was often privileged to enjoy the hospitality of the Bureau when he was Director at its regular parties, when he sought to bring together and make welcome visitors from overseas and representatives of the profession in the United Kingdom, and it always was a pleasure to see his obvious interest in and knowledge of his guests. On these occasions he was most ably and charmingly aided by his wife, who will have the sympathy of a multitude of people in the untimely loss she has sustained.

Dr. J. J. GARD, Chief Medical Officer, Australia House, writes: All Australians who have been privileged to meet and appreciate the admirable qualities of the late Brigadier Sandiford during his 10 years' association with the Commonwealth Medical Advisory Bureau will be grieved to learn of his passing. His friendly welcome, personal charm, and genuine interest in the welfare of those who sought the assistance of the organization will be long remembered. One must pay tribute to the splendid liaison that the Bureau under his guidance has established with the various institutes, colleges, and faculties which has contributed so much to the advance of postgraduate education. Under his personal guidance the organization has contributed greatly to the welfare of overseas postgraduate visitors. He has rendered generous assistance in the pressing problems of accommodation and assimilation. His own personal efforts so ably assisted by his staff in arranging introductions to fellow students and prominent members of the profession in Britain by those periodical social gatherings has greatly contributed to the successful accomplishment of the aims of the organization. I have on several occasions been privileged to be a guest at these functions and have a sincere personal appreciation of Brigadier Sandiford's magnificent contribution to the development of medical education and mutual understanding between practitioners from every part of the British Commonwealth.

Sir KENNETH GOADBY, K.B.E., M.R.C.S., L.R.C.P.
L.D.S. R.C.S.

Sir Kenneth Goadby, who died at Walton-on-the-Hill, Surrey, on August 10 at the age of 85, was both medically and dentally qualified. During the early part of his career he was a bacteriologist with a special interest in oral hygiene. Later he became an expert on industrial poisoning. For many years past he had practised as a physician in Harley Street.

Kenneth Weldon Goadby was born at Gravesend, Kent, on March 7, 1873, the son of the Rev. J. J. Goadby, and was educated at Henley-on-Thames Grammar School and at the University Extension College, Reading. He received his medical training at Guy's Hospital, qualifying first as a dental surgeon by taking the L.D.S. of the Royal College of Surgeons of England in 1896. Four years later he obtained the M.R.C.S., L.R.C.P., and in 1901 he took the D.P.H. of the University of Cambridge. From 1899 to 1902 Goadby worked as a bacteriologist at Guy's Hospital, and in 1900 he was awarded the John Tomes Prize of the Royal College of Surgeons of England for original dental research worthy of special recognition. From 1902 to 1912 he was

lecturer in oral hygiene at the London School of Hygiene and Tropical Medicine. In 1904 he was appointed lecturer in bacteriology at the National Dental Hospital, and in 1907 delivered the Erasmus Wilson lecture on pyorrhoea alveolaris, and in 1911 a Hunterian lecture on the association of diseases of the mouth with rheumatoid arthritis and certain other forms of rheumatism, both before the Royal College of Surgeons of England. When the British Medical Association met at Oxford in 1904 he acted as one of the honorary secretaries of the Section of Dental Surgery, and he served as a vice-president of the same section at the Annual Meeting of the B.M.A. at Exeter in 1907.

In 1913 Goadby was appointed medical referee for industrial poisoning in the County of London. He had previously reported to the Home Office on the operation of the Phosphorus Rules for match factories, and he was a member of the departmental committee which investigated the causes and pathology of lead poisoning. During the first world war he was honorary bacteriological specialist for vaccine therapy at the Royal Herbert Hospital, Woolwich, and a member of the War Office committee for the study of tetanus. At this time he published several papers describing the results of his research on the bacteriology of war wounds. He was also a member of the advisory committee to the Secretary for Mines at the Board of Trade on conditions in metalliferous mines. For his services during the war he was appointed K.B.E. in 1918. His publications included *Mycology of the Mouth* (1903), *A Manual of Industrial Lead Poisoning* (with T. M. Legge) (1912), and *Diseases of the Mouth and Oral Mucous Membrane*, the fourth edition of which appeared in 1931. A former president of the Scientific Film Association, he served as a member of the B.M.A.'s Film Committee in 1951.

Sir Kenneth Goadby married Constance Eva, daughter of Mr. G. Olding, in 1898, and had one son, who is a physician at St. Thomas's Hospital.

M. A. SMITH, M.R.C.S., L.R.C.P.

Dr. M. A. Smith, who in the early years of this century was medical officer to the British Legation at Bangkok and physician to the Court of Siam, died at his home at Ascot on July 24, aged 82. A zoologist of international renown, he was an authority on reptiles, being first president of the British Herpetological Society.

Malcolm Arthur Smith was born in 1875 and was a medical student at Charing Cross Hospital, qualifying in 1898. After holding the posts of house-physician and house-surgeon at Charing Cross he went out to the Far East, first to Singapore and then to Bangkok, where he was medical officer to the British Legation and physician to the Court of Siam. His knowledge of the reptiles of the Far East was prodigious, and he was one of the leading British herpetologists. His book, *The British Amphibians and Reptiles*, is the standard work of reference on the subject, and he published a great number of papers in zoological and other journals. He described his years in Bangkok in a book which appeared in 1946.

Dr. Smith returned to Britain in 1925 and worked for a time at the Natural History Museum. The first president of the British Herpetological Society, he was editor for some years of the *Zoological Record* and zoological secretary of the Linnean Society.

Dr. H. A. REID writes from Penang: Dr. Malcolm Smith, who was generally recognized as the foremost world authority on sea-snakes, was in his 80th year when I had the privilege of first meeting him. At a memorable lunch in his charming Ascot house he recalled with fascinating clarity his earlier work some 40 years previously when he was physician to the Court of Siam and the British Legation at Bangkok. A keen naturalist, he had already contributed a number of distinguished papers on reptiles of the Far East, when he paid special attention to the sea-snakes. He visited many remote fishing villages in Thailand and made a large

collection of sea-snakes which he presented to the British Museum (Natural History). Subsequently he visited all the great museums of the world, collecting information for his classical monograph on the sea-snakes published in 1926. His collection of prepared sea-snake skulls—also presented to the British Museum (Natural History)—must be the finest in the world. A most unassuming and charming man, he retained his intellectual vigour to the last. His writing and conversation were delightfully clear, precise, and to the point. His book on the reptiles of the Far East (Volume 3, *Serpents in the Fauna of British India, Ceylon and Burma including the whole of the Indo-Chinese subregion*.—*Reptilia and Amphibia*, 1943, London) was another classical work—unfortunately now out of print. His death is a great loss to zoology and to his many friends throughout the world.

GEORGE HALL, M.D., F.R.C.S.C.

Dr. George Hall, who was in general practice at Montreal for very many years, died there on June 20. He was 85 years of age.

George Hall was born at Ethel, Ontario, in 1872, and was educated at Riverside School, Montreal High School, and at the University of Bishop's College. Graduating M.D., C.M. from the University of Montreal in 1896, he held the post of house-physician at the Western General Hospital, Montreal, and then came to Great Britain, obtaining the Scottish triple qualification in 1898. A year as an assistant in general practice at Pitlochry, Perthshire, followed, before he returned to Canada to establish himself in general practice at Point St. Charles, in the province of Quebec. Later he moved to Montreal. For some years he was demonstrator in histology and lecturer in physiology in the University of Bishop's College. In 1905 he was granted the degrees of M.D., C.M. *ad eundem*, of McGill University. His chief interest in his long professional career lay in the field of obstetrics, and for many years he examined in the subject for the College of Physicians and Surgeons of Quebec. It was as an obstetrician that he was admitted a Fellow of the Royal College of Physicians and Surgeons of Canada in 1945. A keen member of a number of local medical societies and of the British Medical Association and the Canadian Medical Association, he had the gratification of being presented to the annual general meeting of the C.M.A. in 1955 as the senior member for Quebec.

P. C. FENWICK, C.M.G., M.D., F.R.C.S.Ed.

Dr. P. C. Fenwick, who was director of the radio-therapeutic department of Christchurch Hospital, New Zealand, for a quarter of a century, died on July 5.

Percival Clennell Fenwick was born in London in 1870, the son of Dr. Samuel Fenwick, and was educated at University College, London, receiving his clinical training at St. Thomas's Hospital. He qualified M.R.C.S., L.R.C.P. in 1894 and obtained the London M.B. in the following year. Elected F.R.C.S.Ed. in 1900, he was granted the M.D. degree of the University of New Zealand in 1908, having previously been granted the degrees of M.B., Ch.B. *ad eundem*. After qualification he held the appointments of junior (later, senior) obstetric house-physician at St. Thomas's Hospital and clinical assistant at Brompton Hospital and the Evelina Hospital for Children, and he then acted as a ship surgeon for a time. In 1895 he was appointed assistant resident medical officer at Christchurch Hospital, New Zealand, becoming surgeon in the following year. From 1899 to 1902 he served in South Africa as a surgeon captain in the 2nd New Zealand contingent, and towards the end of hostilities was plague officer at East London. For his services he was awarded the Queen's medal with four clasps. He also acted as war correspondent for a New Zealand syndicate. He was in private practice at Wanganui from 1902 to 1906, and thenceforward until 1924 at Christchurch, where, from 1912 to 1924, he was honorary surgeon to the hospital, then becoming honorary consulting surgeon. He introduced the

use of radium to New Zealand medical practice, and in 1924 founded the radiotherapeutic department at Christchurch Hospital, of which he was in charge from that year until 1948. Serving throughout the first world war, with the rank of colonel, in Egypt, France, and Belgium, he was also in the first New Zealand boat to land at Gallipoli, leaving with the evacuation party. From 1916 to 1919 he commanded New Zealand general hospitals in England, No. 3 at Codford and No. 1 at Brockenhurst. For his war services he was appointed C.M.G. in 1916. Returning to New Zealand after the war, he was assistant director of medical services of the Southern Command in the Dominion from 1922 to 1926, and honorary surgeon to the Governor-General from 1925 to 1930. Soon after he settled in New Zealand he became an honorary life member, lecturer, and examiner of the St. John Ambulance Association, and from 1929 to 1937 was honorary chief commissioner of the Boy Scouts' Association in the Dominion. He was also a lay canon in Christchurch cathedral, and a justice of the peace. He was the author of *A History of Christchurch Hospital*, published in 1924, and *A Review of the Radium Department*, which appeared in 1927. He married Miss Nona E. Wright in 1903 and had one son and one daughter. Mrs. Fenwick died in 1938.

A. J. ORCHARD, M.B., C.M.

With the death of Dr. A. J. Orchard, Christchurch, New Zealand, has lost another well-known medical man. He had been in practice there for nearly sixty years, and died at Calvary Hospital on July 11 at the age of 83.

Albert John Orchard was born at Elmore, a country town in the State of Victoria, Australia, but moved to New Zealand with his parents in 1886. From Christchurch Boys' High School he entered Edinburgh University as a medical student, and graduated M.B., C.M. in 1896. He then returned to Christchurch, where he was in practice until a few weeks before his death and where he was formerly honorary surgeon to the public hospital. During the first world war he served as a captain in the New Zealand Medical Corps in England and at the front. When he returned to civilian life he became a foundation member of the Christchurch Returned Services Association, and for many years was one of the association's medical advocates before the War Pensions Appeal Board. A prominent member of the Methodist Church, he was for a long time chief medical officer of the church's supernumerary fund board. Keenly interested in cricket and, in later life, in bowls, he was president of the East Christchurch cricket club for fifty years: in fact, he was the club's only president from its foundation until his death. Genial and generous by nature, he gained many friends not only among his colleagues but among his patients also. The doyen of his profession in Christchurch, he gave of his best at all times, and his passing has deprived the community of the services of a dependable practitioner of the old school. His many years of practice were officially recognized in 1956, when he was appointed O.B.E. in the Birthday Honours list. He is survived by four sons and three daughters and his sister, Dr. Ethel A. Orchard, who is in practice in Christchurch. Two of his sons, Dr. David E. Orchard and Dr. Geoffrey Orchard, have followed him into the medical profession, and the latter was in partnership with his father.

G. F. LONGBOTHAM, M.B., C.M.

Dr. G. F. Longbotham died at his home at Middlesbrough on August 2. He was 87 years of age.

George Francis Longbotham came of a medical family, and was born at Seaton Carew, in County Durham, on November 9, 1870. He spent his boyhood in Middlesbrough, where his father was in practice and medical officer to what has now become the General Hospital. After going to Epsom College, where his love of athletics became apparent, and after a brief spell of training as a mining engineer, he graduated M.B., C.M. at Edinburgh University in 1892 at

the age of 21. He then held the appointment of house-surgeon at the North Riding Infirmary, Middlesbrough, receiving at the end of four years the unusual distinction of being presented with an illuminated address. After experience as an assistant in various practices, he started in practice in Middlesbrough, where he was to work for the rest of his career. He was appointed surgeon to the North Riding Infirmary, and played a considerable part in the organization and surgical work of the Carter Bequest Hospital, a small hospital open to all practitioners. When the Middlesbrough Maternity Home was opened he became its first consultant.

B. W. writes: By the death of Dr. Longbotham, Tees-side has lost one of its best-known and respected practitioners. In addition to running a busy practice, he did a large amount of surgery and obstetrics. He read widely and knew the works of Smellie well, and kept up to date. He was the first person in Middlesbrough to remove tonsils, he went to Manchester to see Fothergill do his repair operation, and he was doing lower-segment caesarean sections long before the operation was accepted everywhere in this country. In the first world war he served as surgical specialist at Catterick. He was particularly interested in the work of the Middlesbrough Maternity Home, and presented some of the equipment used there. He showed great kindness to his patients in the grim days of the Tees-side depression. Carrying on his surgical and obstetrical work up to quite recent years, he shared with his partners in the work of his large general practice up to a few months ago. He was a typical example of the best type of the old school of practitioner, hard-working and self-reliant, operating on patients in their homes if that seemed advisable. Though he saw clearly that times had changed and that more specialization had become necessary, he did not take kindly to some modern trends in medical practice. Finding relaxation in sport and athletics, he was a keen supporter of Association football in Middlesbrough, and up to quite recently attended athletic meetings and entertained visiting athletes. He found great pleasure in the athletic achievements of his sons, and his family life was a happy one, though he was saddened by the death of his wife a few years ago after a long illness. His son, Dr. Basil Longbotham, is well known in Middlesbrough, and continues in the family practice.

H. M. BERNCASTLE, M.R.C.S., L.R.C.P.

Dr. H. M. Berncastle, who died on August 4 at the age of 91, was formerly medical superintendent of the Croydon Mental Hospital (now Warlingham Park Hospital).

Herbert Melbourne Berncastle, the son of a doctor who had at one time practised in Croydon, was born on August 4, 1867, in Sydney. Before becoming a doctor in what he used to refer to as his "salad days," he followed a seafaring career. He trained in sail, obtaining a Board of Trade first mate certificate in 1890. He and the late Dr. Stephen Rowland were probably the last medically qualified holders of the square-rigged certificate. During the South African War he was the master of a vessel engaged in transporting troops to South Africa. At the age of 26 he became a medical student at Guy's Hospital, from which he qualified in 1899. After holding the post of house-surgeon at the Essex County Hospital at Colchester, he joined the medical staff of the Croydon Mental Hospital in 1903 as assistant to Dr. E. S. Pasmore, the first medical superintendent. On the death of Dr. Pasmore in 1927 Dr. Berncastle was appointed medical superintendent, a post he worthily held for eight years until his retirement in 1935.

W.H.S. writes: Dr. Berncastle will be remembered as being one of the kindest of men and a delightful person to know, possessing as he did originality of ideas and being an excellent raconteur. He maintained his interest in the Warlingham Park Hospital throughout his long retirement, and, indeed, until only two years ago, when increasing infirmity made this no longer possible, regularly attended the annual dinners. At the age of 90 he contributed an interesting article to the *Guy's Hospital Gazette* in which he

gave what he regarded as his secret of longevity. His wife died while they were living for a while during the second world war at Bournemouth, and he leaves three sons.

H. SINIGAR, M.D.

On August 8 Dr. Harry Sinigar died at his home at Gerrard's Cross in his 88th year. Many years ago he was asked by a friend whether his rather unusual surname was English. To this he replied, "Well, my people have been in Dorset for the last 700 years, to my knowledge," and went on to explain the origin of the name. They had been for centuries hereditary wardens at the Abbotsbury swanneries, and the Norman-French *cygne-garde* had been anglicized to Sinigar. His startling blue eyes, ruddy complexion, and blonde colouring suggested Saxon origin.

Harry Sinigar was born on August 27, 1871, in Birmingham, where his father, George Wintle Sinigar, was a corn merchant. From King Edward's School, Aston, he went on to study medicine at the old Mason's College, Birmingham, before the creation of the University; there he won an entrance scholarship. Thence he went to University College, London, and from there took the London M.B. with honours in 1895, having already qualified M.R.C.S., L.R.C.P. in 1893. He proceeded to the M.D. in 1898 and to the D.P.H. in 1902. He was house-surgeon at the Queen's Hospital, Birmingham. Then he became medical officer at the St. Marylebone Infirmary, now St. Charles's Hospital, Notting Hill. Here he attained the grade of deputy superintendent, but resigned to begin general practice at Southall, Middlesex. Eventually he was appointed a regional medical officer of the Ministry of Health. Essentially modest and unassuming, his friends knew that he was a practitioner of much more than average competence. For many years he lived at Gerrard's Cross, after his retirement; his garden and a game of bridge were his principal recreations. He was a staunch supporter of both the chief medical charities: Epsom College, especially, has reason to deplore his decease. He was unmarried.

P. P. DEBONO, O.B.E., M.D., F.R.C.S., D.P.H.

Dr. WILLIAM SPITERI writes: Professor P. P. Debono, whose obituary was printed in the *Journal* of August 9 (p. 392), was my colleague and treasured friend from childhood. We went to the same school and university in Malta together and we obtained our M.D. about the same time. Always a very zealous student, with a splendid memory and intelligence as well as wisdom, he passed with flying colours after two years the three-year course in science preparatory to the academical course of medicine, a feat never tried before. Peter Paul was always top dog at school and also at the university. At the final examination for the M.D. he came first with another colleague of ours, Dr. P. Xuereb. I tender my heartfelt sympathies to Mrs. Debono and all other relatives.

J. L. SHELLSHEAR, D.S.O., M.D., M.S.

Sir GORDON GORDON-TAYLOR writes: To the excellent obituary notice of Professor J. L. Shellshear which appeared in the columns of the *B.M.J.* of August 16 perhaps I may be permitted to add a further short tribute. Your correspondent alludes to "his infectious keenness in his department" in Hong Kong, but this was equally manifest in Sydney at the close of the 1939-45 war, and there must be many young surgeons of the many H.M. ships gathered in Sydney Harbour who still remember with gratitude how he threw open to them the doors of the anatomical department of Sydney University, and even held classes for those whose eyes were directed towards the distant goal of the Primary Fellowship in London. I have in my possession specimens of the notes which he issued to the young surgeon-lieutenants and lieutenant-commanders for their instruction. Till the

close of his life he retained a paternal interest in the anatomy department of Sydney, and only some months ago wrote to me of the great improvements in the teaching there under Professor MacIntosh. Not unnaturally he was proud of his beautiful city, and several lantern slides which he sent me of its harbour are in my hand as I write this farewell to my old friend "Joe" Shellshear.

Medico-Legal

A MISUNDERSTOOD PRESCRIPTION

[FROM AN EXPERT IN FORENSIC MEDICINE]

In February of this year a man of 64 was admitted to hospital for treatment of his hypertension. The routine for such cases was to give them, in the first instance, tablets of "ansolysen" (pentolinium tartrate). The senior house officer therefore wrote on the patient's treatment card "Ansolysen 40 mg. t.d.s." The method of administration was not otherwise stated. Of the two sisters in charge of the ward, one was on holiday and one off duty on the evening of February 13. The staff nurse on duty had no previous experience of treatment with ansolysen and, finding no tablets of ansolysen in the place where drugs for the ward were usually kept, but seeing a bottle of liquid ansolysen, she decided to give the drug by intramuscular injection. She accordingly injected 40 mg. of ansolysen at 6 p.m. Five minutes later the patient complained of abdominal discomfort and dizziness, his blood pressure could not be recorded, and, although treatment with mephentermine and noradrenaline did in fact raise his blood pressure to recordable levels for a short time, he died some six hours later.

Post-mortem examination showed the presence of a recent red blood clot, two inches (5 cm.) from the origin of the anterior branch of the left coronary artery. The pathologist gave the cause of death as coronary thrombosis following the administration of a hypotensive drug. In addressing the jury the coroner said: "You may think it is not beyond the bounds of human ingenuity that doctors give clearly and concisely which way a drug is to be used." The jury returned a verdict of death by misadventure.

Comment

The abbreviation "t.d.s." for *ter die sumendum* is an expression with which doctor, nurse, pharmacist, and many a lay person are perhaps all too familiar—the literal translation is, of course, that the drug should be "taken," not "given." Historically these abbreviations were used as instructions to pharmacists who translated them into English for the information of the patient, presumably to maintain the air of mystery and intellectual superiority of both professions. It is probably asking too much to expect a nurse to know the precise meaning of this abbreviation, and the suggestion of the coroner was that the further abbreviation "tab." should have prefixed the prescription and that this might have prevented the accident. On the other hand, if she was in doubt, the nurse could have asked the house officer, who was readily available, and also she did not know, as she should have done, that after 5 p.m. she could still obtain from the pharmacy drugs needed in the ward.

This case is another example of those misunderstandings which account for so many iatrogenic disasters—mega units are mistaken for thousands of units of penicillin, ounces of paraldehyde are confused with drachms, pure adrenaline is used instead of a dilution of 1 in 1,000. With the complete replacement of the Apothecaries' Weights and Measures by the Metric System, it is possible that even more confusion may occur in the future, and the time may well have come seriously to consider rationalizing the instructions for the administration of drugs.

The responsibilities of nurses are much greater now than 20 years ago, partly as a result of the introduction of potent new drugs, many of them given by injection. Ought we, then, to add to the unavoidable risks of therapy by clinging to traditional but possibly confusing abbreviations when writing prescriptions, or worse still by coining new ones? Is it not high time, in fact, that instructions for treatment were always written in plain English, and abbreviations altogether avoided?

Universities and Colleges

UNIVERSITY OF OXFORD

In Congregation on August 2 the degree of D.M. was conferred on G. A. Rose, and the degree of B.M. on M. A. Pratelli.

The Medical Scholarship for 1958 has been awarded to Edmund Neville Hey, Scholar of Magdalen College, and the Theodore Williams Scholarship in Physiology for 1958 to William Ronald Aylett Muntz, Scholar of Worcester College.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly Comitia of the College, held on July 31, the President, Dr. Robert Platt, was reappointed the College representative on the governing body of the British Postgraduate Medical Federation; Dr. S. W. Davidson on the council of King's College, Newcastle upon Tyne (University of Durham); and Dr. R. E. Lane the representative of the three Royal Colleges and the Society of Apothecaries of London on the Industrial Health Advisory Committee for three years. Dr. C. E. Newman was appointed the College representative on the advisory board of education of the Royal College of Nursing.

Sir Russell Brain was appointed Harveian Orator and Professor A. Kekwick Bradshaw Lecturer, both for 1959.

The following Lecturers were also appointed: For 1959, Lumleian, Professor E. J. Wayne; Goulstonian, Professor W. S. Peart; Oliver-Sharpey, Dr. P. L. Mollison; Lloyd-Roberts, Sir Kenneth Clark; Humphry Davy Rolleston, Professor J. F. Brock. For 1960, Croonian, Professor D. E. Denny-Brown; FitzPatrick, Dr. K. D. Keele; Watson Smith, Dr. F. R. Bettley; Marc Daniels, Professor J. W. Crofton.

Dr. Saul Adler was admitted, *in absentia*, to the Fellowship of the College.

It was announced that the Murchison Scholarship for 1958 had been awarded to Dr. Lionel G. Whitby.

Licences

Licences to practise were conferred upon the following 125 candidates who had passed the final examination in medicine, surgery and midwifery of the Conjoint Board and who have complied with the by-laws of the College:

A. R. Adamson, R. Allay, A. J. R. Anderson, A. L. Ansdell, J. T. Aroney, J. S. Bailey, E. A. Bamgboye, J. E. Banatvala, M. D. Beagley, L. S. Bernstein, W. H. Bevan-Thomas, G. A. Bewley, W. M. Bodger, P. R. Brass, R. C. Bredday, P. D. G. Briggs, F. H. Brindle, M. H. Brooke, F. T. Brough, M. H. Bull, R. W. Burt, L. J. Burton, W. D. Callum, I. G. Carnegie Brown, I. G. Christie, P. W. Clements, D. L. Common, D. Connan, Edith M. Cooke, J. C. Couve de Murville, P. A. Cullum, T. O. Dada, Pauline M. H. Davidson, N. A. De Heer, Edna M. Dunn, A. J. Earl, R. J. Earlam, D. J. Eilam, R. C. Evans, R. J. Evans, R. E. Fallowfield, M. Fisher, H. J. L. Francis, P. Fursdon, H. A. Garfinkel, P. B. Garland, P. M. Geipke, J. M. Goyder, J. Grant, R. S. Greenwood, J. S. Grimshaw, A. C. Halliwell, J. D. Hardcastle, D. C. Harvey, A. L. Hovenden, Anne T. Irvine, Anne Jacques, S. A. Janmohamed, I. N. L. Johnston, Jane M. Jones, Winifred N. Kaine, N. B. Kirkland, Hilda Koilpillai, L. Kwasny, Andrea M. D. Langford, R. Larizadeh, N. K. Leiper, D. W. Lewis, C. M. Liassides, P. O. Liebling, M. Lindsey, Marion R. List, T. A. Lloyd-James, A. M. Lush, D. B. Macadam, B. J. T. McAvo, C. E. Macdonald, J. W. Mack, K. V. Mellor, D. Mercer, A. R. Molyneux, Pauline S. Monro, H. G. Morgan, G. Moses, I. S. Muir, M. Y. Najjar, A. I. Nwabueze, N. W. Oakley, K. A. Olafinuhan, E. O. Olorin, S. B. Oni, B. A. Oni-Okpaku, E. H. Osborn-Smith, J. D. Owen, Glenys R. Packer, N. D. Parkin, M. G. O. Parrish, B. Pitt-Payne, D. Powell, J. N. Powell, E. B. Raftery, M. J. Ramsden, D. J. Richards, J. M. R. Ridley, R. K. Saksena, N. Sakaraya, M. A. Sasson, D. C. L. Savage, M. Segal, R. I. D. Simpson, Margaret R. Skelton, B. R. T. Smith, J. M. Stephenson, J. M. Taylor, Geraldine Thomas, J. B. Traherne, W. J. Trowell, G. L. Tullett, F. N. Udeh, A. C. Upjohn, S. K.-C. R. Villavarayan, Daphne M. Ward, P. H. Waterfield, W. F. Whimster, R. Yeo.

Diplomas

The following diplomas were conferred jointly with the Royal College of Surgeons of England:

DIPLOMA IN ANAESTHETICS.—K. C. Ararwala, A. A. A. Al-Uzri, B. R. Baliga, F. E. Bennetts, E. P. Berwick, F. R. Bhupalan, Maryrose, E. Brewerton, P. Brine, E. F. Brooks, Georgina D. Brown, T. H. L. Bryson, J. G. Camilleri, W. F. Carpenter, G. Cartmel, Pamela Channon, F. B. N. Clarke, A. J. Clement, E. Clissold, R. J. H. H. Colback, C. F. Conway,

Marian H. Dadaczynski, J. P. Davie, I. B. Denny, G. R. Dow, T. Dowell, A. J. F. Eberle, N. L. Edmond, H. J. Ellis, Myrtle Farquharson, E. L. Fischer, F. Fisher, Freda W. Fleming, J. W. Gamble, D. N. Ganguly, M. A. Gilbert, Heath P. Gillespie, G. B. Gillett, J. A. M. Goodwin, B. G. H. Grant, A. Gupta, M. Haase, R. L. Hargrove, Pamela A. Harris, Sylvia K. Hepton, E. Holmes, Bridget A. Jepson, H. W. F. Jones, Margaret L. L. Jones, Olive C. Jones, S. A. Kabir, K. R. Kamath, N. Kaplan, S. A. Khan, P. F. Knight, R. F. Knight, J. R. Lawrance-Owen, M. G. Leonard, R. N. Lewis, J. G. Lindsay, J. H. L. Lloyd-Thomas, J. N. Lunn, A. J. McDonald, H. McIntyre, T. D. M. McNeill, Frances M. McQuitty, S. W. McVicker, J. Mackett, R. E. Maclaurin, H. A. Maher, I. M. J. Mair, Ma Shu Poh, K. Mustafa, M. L. Nene, B. E. Ohmacht, G. D. Parbrook, D. A. Patelle, Audrey M. Peeling, P. A. Pelham, Margaret E. Pickering-Pick, W. M. Pillow, Lora Y. Pratt, P. B. W. Price, D. Proctor, A. Rieck, Brenda K. Rimmer, R. S. Ritchie, Pamela D. Roberts, Anna I. Robertson, Sheila J. B. Robertson, R. H. Robinson, D. Saltoun, Betty V. Scott, R. O. Selby, H. W. Stark, J. G. Thomson, L. G. von Thomann, Alice van Waterschoot, H. J. White, Anne M. Wilson, G. R. V. Worrall, P. R. Wykes, Ming-Hon Yeung, R. Zeeher.

DIPLOMA IN CHILD HEALTH.—J. T. Binless, D. G. Cottom.

DIPLOMA IN INDUSTRIAL HEALTH.—P. G. Cannon, J. K. Chakravarti, A. J. Hibell, P. G. W. A. Lommerse, H. F. McElligott, M. A. Malik, A. C. Reith, M. M. Tint, J. de M. Vink.

DIPLOMA IN LARYNGOLOGY AND OTOTOLOGY.—L. R. Agrawal, B. Alam, A. A. Anderson, P. J. Batchelor, P. G. A. Bloomer, R. C. Bloomfield, J. T. Buffin, R. M. C. Butler, S. R. S. Chandrasekhar, G. W. S. Choa, M. G. Cox, T. J. Crowe, C. E. Gabriel, D. P. Ghosh, D. J. Godfrey, A. N. Goshennin, R. L. Gupta, P. C. Leeson, B. Livesey, M. B. Stanton, Brenda L. Stather-Dunn, J. B. Walker.

DIPLOMA IN MEDICAL RADIOLOGY.—W. W. M. Abeysekera, D. M. Alexander, T. P. Banerjee, D. M. Brebner, P. M. Bretland, J. A. D. Briggs, F. K. Downsborough, H. E. Engelbrecht, I. H. Lawrence, K. M. Mayo, J. G. A. Monks, A. K. Mukhopadhyay, R. M. Murray-Leslie, B. K. N. Murthy, K. Pasupathy, E. J. Pick, R. G. Pitman, D. H. Provan, J. F. Ryan, Muriel E. Sidaway, W. Wilson, F. W. Wright.

DIPLOMA IN MEDICAL RADIOTHERAPY.—P. Banerjee, J. S. Bunting, J. C. McI. Fenterly, G. A. Li-G. Glazebrook, N. Halazonetis, N. MacLeod, Dorothy S. Murrell, S. Nissanga, T. A. O'Donnell.

DIPLOMA IN OPHTHALMOLOGY.—D. E. P. Jones.

DIPLOMA IN PATHOLOGY.—T. Gordon, C. Isaacson, H. Richmond, T. G. Scott, D. K. Sen, G. Taylor, P. Thillainathan, C. A. H. Trench.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—H. A. Anderson, Margaret L. Arden, J. K. Binna, Asuncion P. Cheyne, Marion B. Coleman, Mary J. Collins, G. E. Cook, H. Davidian, Margaret McC. Dewar, D. Duncan, R. L. Duncan, J. P. Farrell, P. G. Fawcett, K. M. Fraser, Pearl Goddard, H. S. Greer, J. G. Hegarty, I. A. Horton, L. C. Hurst, M. S. R. Kamal, K. E. Le Page, J. Lister, E. B. McDowall, Agnes M. McGlashan, L. E. McLaughlin, Beryl Margolis, R. Middlefield, Helen M. P. Molony, J. S. V. Mouat, E. W. P. Noall, D. P. Oakley, R. H. V. Ollendorff, H. I. H. Porcher, S. G. Rowe, A. Sinclair, F. G. Spear, A. Stevenson, M. H. Sunderland, E. L. Sutherland, R. P. M. Urquhart, P. K. G. Warren, J. M. Woodforde, A. R. Worters, W. B. Wright.

DIPLOMA IN PUBLIC HEALTH.—Grace V. Andrew, A. W. B. M. Ariff, Rosemary A. Begg, J. T. Cecil, G. F. Devey, Sheila H. E. Fairweather, R. Gracias, C. Harris, V. A. Lloyd, M. H. Mahmoud, R. G. Newberry, R. A. Ryan, Z. Q. Shaikh, J. B. Stafford, A. W. Tranter, J. Waters.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on July 31 with Sir James Paterson Ross, President, in the chair, a diploma of Fellowship was granted to Padmanabhen Narendran, of the University of Madras.

Diplomas in Anaesthetics, in Industrial Health, in Laryngology and Otology, in Medical Radiodiagnosis, in Medical Radiotherapy, in Pathology, in Psychological Medicine, and in Public Health were granted jointly with the Royal College of Physicians of London to the successful candidates whose names are printed above in the report of the meeting of the Royal College of Physicians of London, also held on July 31.

Vital Statistics

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the years 1949-57 are shown thus ----, the figures for 1958 thus —. Except for the curves showing notifications in 1958, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Week Ending August 9

Infectious diseases were notably less prevalent in England and Wales during the week ending August 9 than in the previous week. Falls in the number of notifications included 142 for scarlet fever, from 552 to 410; 102 for whooping-cough, from 709 to 607; 721 for measles, from 6,299 to 5,578; 169 for dysentery, from 536 to 367; 18 for acute pneumonia, from 168 to 150; and 90 for food-poisoning, from 261 to 171.

Notifications of acute poliomyelitis rose by 8, from 65 to 73. The paralytic cases increased by 14, from 37 to 51; while the non-paralytic cases fell by 6, from 28 to 22. The largest returns of acute poliomyelitis were from Yorkshire West Riding, 18 paralytic and 3 non-paralytic cases. The majority of these cases were in Leeds C.B. 8 and Halifax C.B. 3. Lancashire notified 10 cases (Manchester C.B. 3, Liverpool C.B. 2).

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Hypotensive Drugs in General Practice

Q.—What hypotensive drugs are suitable for use in general practice, and what are their respective indications?

A.—Any of the newer hypotensive drugs may be used in general practice, but the ganglion-blocking agents present some practical difficulties in view of their side-effects and the necessity for frequent observation and control of dosage. Of the drugs which do not act by producing ganglion blockage, reserpine is a useful, but mild, hypotensive agent which exerts its best effects in combination with a powerful ganglion-blocking agent such as pentolinium. It also has a sedative action which is useful in nervous and apprehensive patients. Minor side-effects such as nasal congestion and diarrhoea may occur, but in a few cases serious mental depression may result, and patients should be warned to discontinue the drug if they become depressed. It should not be given to patients with a history of mental instability. Occasionally tremor and rigidity of striatal type may develop. Patients with heart disease should be instructed to restrict their intake of salt when taking reserpine, as the drug tends to cause salt retention and may thus aggravate or precipitate congestive heart failure. The dose should never exceed 0.25 mg. three times daily. Reserpine is suitable for use in patients with uncomplicated hypertension of mild or moderate severity which is aggravated by anxiety, or for potentiating the action of a ganglion-blocking agent. Reserpine alone is quite ineffective in controlling severe, complicated, or malignant hypertension, and should not be used for this purpose.

Of the ganglion-blocking agents, hexamethonium, pentolinium, or mecamlamine may be used, but their side-effects and the phenomenon of increasing tolerance make initial treatment difficult and time-consuming. Hexamethonium has little place except in the treatment of acute hypertensive emergencies. The injection of 5–10 mg. will often relieve acute hypertensive left ventricular failure by rapidly reducing the blood pressure, and may also be of value in the treatment of acute hypertensive encephalopathy. Pentolinium and mecamlamine are used by mouth in the treatment of severe hypertension complicated by hypertensive vascular disease, such as heart failure, and in malignant hypertension. Treatment is best begun in hospital, where the nature of the hypertension can be fully investigated and treatment guided by frequent blood pressure readings. In the initial stages tolerance develops, and the dosage has to be steadily increased day by day until stabilization has occurred. Treatment is then usually continued at home. Ganglion-blocking agents exert their maximum effects in the upright posture, so that the blood pressure falls on standing up. This postural hypotension is of great importance in the control of high blood pressure, and provides evidence that the ganglion-blocking agent is really working. Some postural dizziness is to be expected in most patients, and other side-effects include dry mouth, constipation, and difficulty in accommodation and in micturition. The most important of these is constipation, which if allowed to go unchecked may lead to ileus, particularly when mecamlamine is used.

Recently the diuretic chlorothiazide has been used to potentiate the effects of mecamlamine, permitting effective blood pressure control with smaller dosage and fewer side-effects. Potassium supplements are essential, as chlorothiazide causes potassium depletion due to urinary loss. Mecamlamine should not be used in elderly patients with severe cerebral vascular disease or renal insufficiency, as it may precipitate acute dementia.

The requirements of ganglion-blocking agents are diminished by dehydration and fever, and thus dosage may have to be reduced if the patient develops an intercurrent infection. For full details of the use of hypotensive drugs the questioner is advised to consult a recognized textbook on the subject.

Psoriasis of the Nails

Q.—A woman with long-standing generalized psoriasis has recently developed pigmentation of the nails of both hands. What can be done to mask the discoloration?

A.—It is presumed that the discoloration of the nails referred to is the brownish-yellow discoloration produced by psoriasis of the nails. Psoriasis of the nails sometimes responds to x-ray treatment, but when the skin lesions have been present for many years it is doubtful whether radiotherapy or any other treatment will have much effect. Discoloration may be, of course, very largely masked by applying nail varnish. If the patient does not like the conspicuous colour of red nails she may apply nail varnish base followed by ordinary colourless nail varnish. This is often used as a means of concealing "milk spots" in the nails, and may well be sufficient to hide the lesions of psoriasis.

Transporting Liquid Oxygen

Q.—What are the hazards of transportation of liquid oxygen by road in the event of a collision spilling the contents?

A.—Liquid oxygen in the crude state has a boiling point of -180°C . When spilled the liquid rapidly evaporates. The major hazards when spilled under the conditions specified would be from burns, either from fire or from splashes with the cold liquid. There is no appreciable toxic hazard. The greatest risk is from fire, and precautions should be taken to prevent exposure to naked lights, etc.

The problems raised by the transport of liquid oxygen have been a subject of much research by chemical and safety engineers and an extensive bibliography exists. Inquiry shows that there has not yet been an incident in which liquid oxygen has spilled out and caused a serious fire during transit. This is doubtless owing to the special method of construction of the road containers.

Tobacco Mosaic Virus

Q.—Is the tobacco mosaic virus communicable to man, and, if so, is it ever pathogenic?

A.—No instance of transmission of tobacco mosaic virus to man has ever been recorded. The widespread distribution of this virus in nature would have provided ample chances for its potential pathogenic role to be observed.

Collected Articles from the "British Medical Journal"

The following books are available through booksellers or from the Publishing Manager, B.M.A. House. Prices, which include postage, are now the same for both inland and overseas.

Emergencies in General Practice (26s. 9d.).

Refresher Course for General Practitioners, Volumes 2 and 3 (26s. 9d.).

Clinical Pathology in General Practice (22s. 3d.).

Any Questions?, Volumes 2 and 3 (8s. 3d. each).

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: *Attilology*, Westcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Director, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. CITRATE INTOXICATION

A CLINICAL AND EXPERIMENTAL STUDY

BY

JOHN LUDBROOK, M.B., F.R.C.S.
Leverhulme Research Fellow

AND

VICTOR WYNN, M.D.
Senior Lecturer in Surgery

From the Surgical Unit, St. Mary's Hospital, London

For many years the sodium salts of citric acid have been used as anticoagulants in blood for transfusion. For the most part it has proved safe to infuse into humans the quantities of citrate contained in stored blood. However, reports of citrate overdose in man. Citric acid forms weakly dissociated salts with divalent cations (Hastings *et al.*, 1934) and its untoward effects are generally attributed to the depression of ionization of such cations in the extracellular fluid, particularly calcium. The excitable tissues of the body are susceptible to such a depression, the effects on cardiac muscle being the most important.

Wexler *et al.* (1949) studied newborn infants with erythroblastosis receiving exchange transfusions of citrated blood. In the course of the transfusions the plasma citrate rose from normal levels of 2 to 3 mg. to 60 to 120 mg./100 ml. In some cases there was associated tetany or convulsions relieved by the infusion of calcium.

Electrocardiographic changes in the course of exchange transfusions were observed by Furman *et al.* (1951) in six infants, four of whom showed muscle tremors and two lengthening of the QT interval. These changes were reversed by intravenous calcium gluconate. Gustafson (1951) observed muscle tremors but no changes in the QT interval in eight infants receiving exchange transfusion. Ames *et al.* (1950) also failed to detect significant E.C.G. changes in infants with plasma citrate levels of up to 53 mg./100 ml.

In adults there have been two extensive investigations: those of Bunker *et al.* (1955) and Howland *et al.* (1957). The former workers studied 130 patients receiving citrated blood, generally in the course of surgery. They calculated the depression of plasma ionized calcium due to citrate from the measured total plasma calcium, protein, and citrate, using the equations of Hastings *et al.* (1934) and McLean and Hastings (1935). The calculated ionized calcium was used to correlate clinical and biochemical findings. At rates of blood infusion of about 500 ml. in 15 minutes the rise in plasma citrate and the depression of ionized calcium was greater in those patients with liver disease than in the remainder. Thus, of the 28 patients in whom the calculated plasma ionized calcium fell below the normal range—that is, less than 0.8 mM/kg. H_2O —17 suffered from liver disease. 2 underwent surgery involving interference with liver

circulation (pancreaticoduodenectomy with portal vein resection, resection of thoracic aortic aneurysm), and 4 had resection of abdominal aortic aneurysms, the surgical details not being given. One patient underwent craniotomy under induced hypothermia to 25.8°C . Those patients with the lowest ionized calcium levels had associated hypotension, in some cases reversed by intravenous calcium chloride.

Howland *et al.* (1957) established normal values for plasma citrate in man (0.80 ± 0.8 mg./100 ml.) and in women (1.08 ± 0.9 mg./100 ml.). By infusion of acid-citrate-dextrose solution (A.C.D.) rapidly into patients they were able to show large increases in plasma citrate with accompanying lengthening of the QT interval, though without detecting tetany or hypotension. They also studied 77 patients receiving citrated blood under anaesthesia and found good correlation between the rate of blood infusion and the plasma citrate level, without, however, observing untoward effects from the raised plasma citrate.

Apart from the above reports, the literature of citrate intoxication in man includes a few incompletely documented cases in which citrated blood was implicated as a cause for cardiac dysrhythmia—for example, Hubbard *et al.* (1956) and Argent (1957).

In summary, it appears from the clinical reports that there may be a marked elevation of the plasma citrate level by the infusion of citrated blood under certain circumstances: in exchange transfusions in infants, and on other occasions when blood or plasma is infused rapidly, particularly in the presence of disease or impaired blood supply of the liver. The signs which have been attributed to citrate intoxication are muscle-twitching or convulsions in the unanaesthetized patient, E.C.G. changes, particularly lengthening of the QT interval leading to cardiac asystole, arterial hypotension resistant to further blood transfusion or pressor agents, and possibly prolongation of clotting-time.

It is surprising, in view of the widespread use of citrated blood and the above reports of toxicity, that the fate of infused citrate in humans is not yet completely known. Salant and Wise (1917), using the rather inexact method of citrate estimation available at the time, studied the fate of brief infusions of citrate into animals. They noted that of an infused dose 4 to 13% was excreted in the urine in rabbits, 30% in cats, and 40% in dogs. They confirmed the previously observed effects of muscle-twitching, convulsions, and cardiac and

respiratory arrest. They also noted that blood itself had little or no power to destroy citrate. Martensson (1940), using a similar infusion technique, found that in the rabbit 4 to 8% of a dose was excreted in the urine, in the cat 27 to 43%. From perfusion experiments he came to the conclusion that the liver had little or no ability to destroy citrate, the kidney a marked ability—results at variance with the work of Sjöström (1937), who obtained nearly complete clearance of citrate from the perfusate in one passage through the perfused liver, and at variance with observations of Bunker *et al.* in man. One conclusion which can be drawn from the animal experiments is that there is a marked species difference in the behaviour of infused citrate.

In this paper we present four clinical cases demonstrating greatly raised plasma citrate levels following the infusion of blood under various circumstances, and an account of some work on the elimination of infused citrate from the plasma in dogs and man.

Material and Methods

The blood used for transfusion was that supplied by the National Blood Transfusion Service. Each 540-ml. bottle contains 1.75 g. of citrate expressed as citric acid.

For the estimation of plasma and urinary citrate the method of Natelson *et al.* (1948) was used, modified to extend the range. Plasma citrate levels are reported as mg./100 ml. of citric acid. Plasma calcium was estimated

FIG. 1.—Changes in oesophageal temperature, blood pressure, QTc interval, plasma citrate, total and ionized calcium in Case 1. Amount of infused blood is shown in 0.5-litre blocks, and duration of aortic clamping and of noradrenaline infusion is indicated.

by the method of Sobel and Sobel (1939). It was found that plasma citrate levels of up to 250 mg./100 ml. did not interfere detectably with calcium estimation, provided the oxalated plasma was allowed to stand for 12 hours at 4° C. before centrifuging. Ionized calcium was calculated from the equations of Hastings *et al.* (1934) and McLean and Hastings (1935). It is realized that this method does not give precise values, but it gives the only measure of ionized calcium in the presence of citrate that is at present available.

Other biochemical estimations were made by methods previously reported from this laboratory (Wynn and Houghton, 1957; Wynn and Ludbrook, 1957). Blood samples were either arterial or were taken from a vein distant to the site of infusion.

The QT interval on the E.C.G. was corrected for heart rate by the formula $QT/\sqrt{R-R}$ and expressed as QTc.

A blood balance by a method of swab weighing was carried out on these patients undergoing surgery.

Clinical Investigation

Case 1

A man of 55 was operated on under induced hypothermia to 29.8° C. for an aortic thrombosis extending up to the level of the renal arteries. Early in the operation 2.2 l. of blood was infused in one hour (1.4 mg. citrate/kg./min.), exactly replacing blood lost. Systolic blood pressure fell from 240 to 100 mm. Hg (Fig. 1). It was noted that on the E.C.G. the QTc interval lengthened from 0.44 to 0.64 sec. (Fig. 2). Calcium gluconate (1 g.) was given at this stage intravenously.

Arterial clamps were placed across the aorta above the renal arteries and on both common iliac arteries for some three hours during the resection of the affected aortic segment and insertion of a homograft. After release of the clamps there was further haemorrhage and 3.25 l. of blood was given in 1.4 hours (1.5 mg. citrate/kg./min.). Blood pressure became unrecordable in the extremities and remained so despite more than complete blood replacement and the infusion of noradrenaline. The QTc interval became lengthened to 0.70 sec., there was excessive oozing from the wound, and the patient died in ventricular fibrillation after receiving 7.5 l. of blood (26 g. citrate). The infusion of 2 g. of calcium gluconate during this latter period was without effect.

An arterial blood sample had been taken prior to the induction of hypothermia, and a further sample was taken during the second phase of rapid blood infusion. Analysis of these samples showed that during this latter period, when citrate was being given at the rate of 1.7 mg./kg./min., the citrate level rose to 140 mg./100 ml., the total calcium from 10 to 13.6 mg./100 ml., while the calculated ionized calcium fell from 1.2 to 0.35 mM/kg. H₂O. The plasma total protein, sodium, potassium, and chloride remained essentially unchanged. The blood pH fell from 7.44 to 7.32.

FIG. 2.—E.C.G.s (lead I) in Case 1 at various times after induction of anaesthesia (see Fig. 1). Note temporary lengthening of QT interval during rapid infusion of blood at 5.8 hours, and grosser changes from 10.1 hours.

It seemed probable to us that citrate intoxication played an important part in this patient's death. We therefore performed plasma citrate estimations on blood samples collected from other patients undergoing operation under hypothermia.

FIG. 3.—Changes in oesophageal temperature, blood pressure, and plasma citrate in Case 2. Amount of infused blood is shown in 0.5-litre blocks. Duration of aortic clamping is indicated.

TABLE I.—Summary of Observations on Case 2. Time Periods are Those Between Arterial Samples, Taken Before Blood was Given, Before Aortic Clamps were Applied, During Clamping, and After Release of the Clamps (See Fig. 3)

	Period Before Clamping (1-2 Hour)	Period During Clamping (2-4 Hour)	Period After Unclamping (2-4 Hour)
Citrate infused (g.)	1.75	5.5	5.5
Rate of citrate infusion (mg./kg./min.)	0.4	0.6	0.6
Arterial plasma citrate at end of period (mg./100 ml.)	11	41	13
Plasma citrate clearance* (%)	65	20	70

* See Discussion.

Case 2

A man of 35 had a syphilitic aortic aneurysm situated in the region of the eleventh to twelfth thoracic vertebrae. At the operation the aorta was clamped above and below the aneurysm, at a level above the coeliac axis. From Fig. 3 aneurysm, at a level above the coeliac axis. From Fig. 3 and Table I it may be seen that, despite the fact that there was no period of rapid blood infusion, at the end of the period of aortic clamping the plasma citrate level had risen to 41 mg./100 ml., and immediately after release of the clamps to 48 mg./100 ml. During an equal period following release of the clamps with an identical rate of citrate infusion the plasma citrate fell to 13 mg./100 ml. The infusion of the plasma citrate remained close to oesophageal temperature throughout.

Case 3

This patient was a woman of 44 with a thrombosis of the abdominal aorta extending up to just below the renal arteries. Under hypothermia (28° C.) a bypass homograft was inserted from the aorta above the coeliac axis to the left external iliac artery. By application of a Crafoord clamp to the aorta it was possible to perform the upper anastomosis without interrupting the aortic blood flow. During 30 minutes after the clamps were released 1,100 ml. of blood was infused (1.9 mg. of citrate/kg./min.). The

plasma citrate rose to 39.5 mg./100 ml. and the calculated rate of citrate removal from the plasma was 65% of normal (see Discussion). There was an associated lengthening of the QTc interval from 0.53 to 0.63 sec., but no significant hypotension.

Case 4

A man of 24 underwent partial hepatectomy for a haemangioma of the liver with associated cirrhosis. Induced hypothermia to 29.5° C. was used. Preoperatively the only defect in liver function detected was a bromsulphthalein retention of 25% after 45 minutes. In the course of the operation the hepatic artery was clamped for 90 minutes. During this period the blood pressure fell, and it remained

FIG. 4.—Changes in oesophageal temperature, blood pressure, QTc interval, and plasma citrate in Case 4. Amount of infused blood is shown in 0.5-litre blocks. Duration of hepatic arterial clamping and of noradrenaline infusion and time of injection of 10 ml. of 10% CaCl₂ are indicated.

TABLE II.—Summary of Observations on Case 4 (see Fig. 4)

	Pre-operative	15 min. After Clamping Hepatic Artery	15 min. After Unclamping Hepatic Artery	24 hr. Later (1 hr. Post-op.)
Oesophageal temp. (°C.)	37	29.5	29.5	32
B.P. (mm. Hg)	120	85	50	110
Rate of citrate infusion (mg./kg./min.)	0	0.4	1.2	0.85
Plasma citrate (mg./100 ml.)	1.6	14.7	70	28.1
Plasma citrate clearance† (%)	—	42	23	42.5
Total plasma Ca (mg./100 ml.)	8.8	8.2	11.0	14.5*

Calculated ionized Ca (mM/kg. H ₂ O)	0.90	0.70	0.50	1.30

* 45 minutes after CaCl₂ infusion. † See Discussion.

low for the remainder of the operation (three hours) despite complete replacement of measured blood loss and the infusion of noradrenaline (Table III and Fig. 4). An intravenous injection of 10 ml. of 10% calcium chloride was followed within a few minutes by a rise in B.P. to 110 to 120 mm. Hg.

Experimental Investigation

1. Citrate in Stored Blood and Plasma

It is known that in normal human blood the citrate ion is virtually confined to the plasma (Natelson *et al.*, 1947). In recently collected citrated blood it was possible to show that at least 98% of the added citrate remained in the plasma. In such blood at 4° C. there was, over a period of three weeks, a progressive fall in plasma citrate concentration to 92% of the original level, but whether this represents metabolic destruction of citrate or a movement into the red cells was not determined.

2. Metabolism of Infused Citrate

When citrate is infused intravenously over a brief period, and the plasma citrate level is measured at intervals following the infusion, there is a very rapid fall of plasma citrate during the first few minutes, which slows until the normal plasma level is regained after about 60 minutes (Mårtensson, 1940; Fig. 7). This rapid disappearance of citrate from the plasma is due to three mechanisms: distribution throughout at least the extracellular space, excretion in the urine, and metabolic destruction.

Bunker *et al.* (1955) observed, as we have, that the plasma concentration after a brief rapid infusion does not exceed that which would be attained if the infused citrate were rapidly distributed in the extracellular space.

In order to eliminate the distribution factor in experiments to determine the rate of metabolic destruction, we have used steady rates of infusion of A.C.D. It was judged that a steady state had been reached with regard to distribution when the plasma citrate and urinary excretion of citrate were constant in successive 10-minute periods. When this steady state is reached, the rate of clearance of citrate from the plasma (excretion plus metabolic destruction) equals the rate of infusion. If the rate of citrate infusion, the plasma citrate, and the urinary excretion of citrate is known, the rate at which citrate is metabolized may be calculated.

FIG. 5.—Relation in two dogs between rate of citrate infusion and plasma citrate concentration. Open circles: dog 1, normal body temperature. Open triangles: dog 2, normal body temperature. Closed triangle: dog 2, hypothermia to 28.5° C. (oesophageal) (see Table III). Each point represents mean value from three plasma samples taken at 10-minute intervals.

Relation of Plasma Citrate Level to Rate of Citrate Infusion.—In both dog and man the rise in plasma citrate was directly proportional to the rate of infusion (cf. Bunker *et al.*, 1955; Howland *et al.*, 1957) (see Figs. 5 and 6). At comparable rates of infusion (1 mg./kg./min.) the elevation of plasma citrate was much higher in the dog (20 mg./100 ml.) than in the human (12.5 mg./100 ml.) (Figs. 5 and 6).

Urinary Excretion.—In the dog at widely differing rates of infusion more or less constant 44% of the infused citrate was excreted in the urine (limits 43 to 48%) (Table III). In normal unanaesthetized man under similar conditions only 18 to 20% was excreted, the remainder being presumably metabolically destroyed. The urine-plasma concentration ratio ranged from 74 to 100 in the dog and from 14 to 25 in the human.

Metabolic Destruction.—It follows from the above that, in man, metabolic destruction is more important as a means of removing citrate from the plasma than in the dog. For a given elevation of plasma citrate the rate of metabolic destruction in man is about twice that in the dog, weight for weight.

Effect of Hypothermia in the Dog.—This was studied in the dog by first determining the rate of metabolic destruction of citrate at normal body temperature, as described above, then repeating a previous rate of infusion in the same animal with its temperature lowered by surface cooling (Table III and Fig. 5). The results show that for the same rate of infusion the rise of plasma citrate was 65% greater in the hypothermic dog, and at equivalent plasma citrate levels the rate of metabolic destruction was 42% lower.

Effect of Hypothermia in Man.—It was not feasible to study this effect by steady infusion. Instead 1.5 g. of citrate was infused in 20 minutes and the fall in plasma citrate followed during the succeeding 40 minutes in three patients before and during hypothermia for carotid disobliteration. A typical result is shown in Fig. 7, demonstrating a similar qualitative effect of hypothermia in man to that in the dog.

Sub-hepatic Temp. °C.	Citrate Infused (mg./kg./min.)	Plasma* Citrate (mg./100 ml.)	Citrate Excreted (mg./kg./min.)	Excreted %	Urine/Plasma Conc. Ratio	Citrate Destroyed (mg./kg./min.)
37.2	0.86	19.5	0.39	45	74	0.47
37.1	2.12	44.6	0.92	48	96	1.20
28.5	0.83	30.5	0.36	43	100	0.47

* These plasma figures are the mean values of determinations made on three samples obtained at consecutive 10-minute intervals. The values did not differ from the mean by more than $\pm 2.5\%$.

Effect of Hypothermia in the Dog.—This was studied in the dog by first determining the rate of metabolic destruction of citrate at normal body temperature, as described above, then repeating a previous rate of infusion in the same animal with its temperature lowered by surface cooling (Table III and Fig. 5). The results show that for the same rate of infusion the rise of plasma citrate was 65% greater in the hypothermic dog, and at equivalent plasma citrate levels the rate of metabolic destruction was 42% lower.

Effect of Hypothermia in Man.—It was not feasible to study this effect by steady infusion. Instead 1.5 g. of citrate was infused in 20 minutes and the fall in plasma citrate followed during the succeeding 40 minutes in three patients before and during hypothermia for carotid disobliteration. A typical result is shown in Fig. 7, demonstrating a similar qualitative effect of hypothermia in man to that in the dog.

Discussion

In the previous section we have defined some of the factors which, during the transfusion of citrated blood, affect the removal of citrate from the plasma and govern its concentration therein. We have found that the rise in the plasma citrate level produced by a steady infusion of citrate is proportional to the rate of infusion. Bunker *et al.* (1955) and Howland *et al.* (1957) have also observed this straight-line relationship (in patients receiving citrated blood). At a citrate infusion rate of 1 mg./kg./min., the elevation of plasma citrate we obtained was 12.5 mg./100 ml. Calculations based upon the data of Bunker *et al.* give a figure of 11 mg./100 ml., and Howland *et al.* reported 8 mg./100 ml.

When the rate of blood transfusion is known, and has been of sufficient duration to allow a steady state to be approached, the difference between the observed and predicted plasma citrate levels allows us to calculate the approximate rate of plasma citrate clearance (excretion plus metabolic destruction) as a percentage of normal, using our results relating the rise of plasma citrate to the rate of infusion (Fig. 6).

With the use of this information it is possible to predict the approximate elevation of plasma citrate produced by a given rate of blood infusion, and to detect and roughly quantitate any defect in the rate of plasma citrate clearance in a patient.

It is difficult to define a dangerous plasma citrate level, but from the observations of Wexler *et al.* (1949), Bunker *et al.* (1955), and ourselves a level of 50 mg./100 ml., giving in a normal person a calculated plasma ionized calcium of about 0.5 mM./kg. H₂O, may be considered at least undesirable. In a normal adult this corresponds to a steady rate of citrated-blood infusion of about one bottle (540 ml.) per five minutes, a rate rarely achieved in practice. It is noteworthy, however, that Argent (1957) and Hubbard *et al.* (1956) have each published an account of a patient undergoing cardiac surgery, during which this rate was attained and in whom ventricular standstill and fibrillation occurred respectively, with reversion to normal rhythm by means of a calcium injection.

It would appear, then, that except at excessively rapid rates of blood infusion some defect in plasma citrate clearance is necessary to produce dangerous levels of plasma citrate. In Fig. 8, in 27 of the 28 cases of which Bunker *et al.* give details, the plasma citrate level is plotted against the rate of citrate infusion and compared with the straight line we have derived for normal man—for example, Fig. 6.

It may be seen that three points deviate grossly from this line. These three patients in fact died during or shortly after surgery with signs consistent with citrate intoxication. They had respectively a resection of a thoracic aneurysm and graft, a pancreaticoduodenectomy and resection of portal vein, and cirrhosis of the liver with bleeding oesophageal varices. Five other points represent patients with a calculated plasma citrate clearance

of less than 50% of normal, while the points representing the remaining patients, many of whom suffered from liver disease, fall more or less along the line of normality.

In Fig. 9 points representing our four patients are similarly plotted. Case 1, in which the blood supply to the liver, kidneys, and lower limbs was impaired for some three hours, shows a gross deviation from normal, and the patient died in circumstances suspicious of citrate intoxication. Case 4, with a hepatic haemangioma and associated cirrhosis, shows a gross defect in plasma citrate clearance immediately after the hepatic artery had been clamped under hypothermia for 90 minutes. This patient had unexplained hypotension reversed by intravenous calcium chloride. From Cases 2 and 3 points are derived showing the effect of hypothermia alone—the plasma citrate clearances are between 65 and 70% of normal at 28° C., a figure consistent with that obtained in the dog for a similar temperature reduction (65%).

Case 4, with pre-existing liver disease, showed a rather lower plasma citrate clearance (42%) under hypothermia. It thus appears that high plasma citrate levels are unlikely to occur with citrated blood transfusion in normal humans, except where the rate of transfusion is extremely rapid (greater than 1 pint (540 ml.) per five minutes in an adult, or during rapid exchange transfusion in infants).

In metabolically abnormal patients, with liver disease, anuria (in view of the fact that some 20% of infused citrate is excreted), or rendered hypothermic, or when there is impairment of liver circulation or application of clamps to the thoracic or high abdominal aorta, the ability to clear the plasma of citrate may be so impaired as to make high plasma citrate levels a real danger. The recognition of the signs of citrate intoxication presents a difficulty, for hypotension may be both the cause for and the effect of rapid transfusion, and, unless a blood balance has been kept, citrate intoxication may be overlooked. The E.C.G. changes from the hypocalcaemia produced by a high plasma citrate concentration—in particular lengthening of the QTc interval, progressing to asystole—may have many other explanations, from hypothermia to hyperkalaemia. Muscle-twitching or convulsions from hypocalcaemia do not appear to occur in the anaesthetized patient, and excessive oozing from the wound is more likely to be due to replacement of the blood volume with stored blood than to a citrate effect.

However, if there are good grounds for suspecting that a high plasma citrate level is the cause of otherwise unexplained hypotension or cardiac dysrhythmia, the logical remedy is the administration of calcium. We prefer to use calcium chloride rather than calcium gluconate, on the ground that the former is more completely ionized. The correct dose can be assessed only by the slow (0.5–1 ml./min.) intravenous injection of 10% calcium chloride, until a response is seen in the blood pressure or on the E.C.G., or until 10 ml. has been given.

Prevention is possible in planned surgical procedures when blood may have to be given rapidly, and when one or more

FIG. 9.—Relation in man between rate of citrate infusion and plasma citrate concentration. Numbered points represent Cases 1 to 4. Dotted circles: hypothermia alone. Closed circles: hypothermia plus impaired liver function. Triangles: hypothermia plus interference with liver blood supply. Note the change in scale of plasma citrate concentration.

of the circumstances which depress the rate of clearance of citrate from the plasma are present, by having available blood collected without the use of citrate. Heparin may be used—though this is often undesirable, particularly in vascular surgery—or blood may be collected over an ion-exchange resin (Walter, 1950). The use of commercial packs for the latter purpose has been satisfactory in our hands, though they are expensive and the blood may be safely stored for only about 10 days.

Summary

High plasma citrate levels occurred during the infusion of citrated blood into four patients undergoing surgery under hypothermia. One patient died with signs attributable to citrate intoxication.

A linear relationship between the rate of infusion of citrate and the rise in plasma citrate level was demonstrated in normal man and dogs. For each 1 mg. of citrate infused per kg. per minute the rise was about 20 mg./100 ml. in dogs and about 12.5 mg./100 ml. in humans.

By using a constant infusion technique it was shown that in dogs some 40% and in man some 20% of infused citrate was excreted in the urine, and the remainder was metabolically destroyed.

In both dog and man hypothermia to 28 to 29° C. was shown to reduce the rate of metabolic destruction of citrate by 30 to 40%.

From our findings it would seem that the infusion of citrated blood at less than about 1 pint (540 ml.) in five minutes in an adult is unlikely to cause a dangerous rise of plasma citrate, provided that the rate of citrate metabolism is not reduced.

Circumstances which impair citrate metabolism in patients are discussed.

We thank Professor C. G. Rob for his encouragement of this study, and Mrs. P. Simpson for her invaluable biochemical assistance. Our thanks are also due to the Ionic Research Unit, Physiology Department, University of Melbourne, and to the Joint Standing Research Committee of St. Mary's Hospital, for grants towards Mrs. Simpson's expenses.

The Ministers of Agriculture and Health and the Secretary of State for Scotland have considered the revised Report of the Food Standards Committee on Copper. They accept the view of the Committee that the consumer will be adequately protected if limits for the copper content of foods which are consistent with good commercial practice are observed and that, in the absence of any new developments, it is unnecessary to give statutory effect to the recommended limits. With certain exceptions these are: beverages ready to drink, 2 p.p.m.; other foods, 20 p.p.m.

SOME AETIOLOGICAL ASPECTS OF CORONARY HEART DISEASE

AN INDIAN POINT OF VIEW BASED ON A STUDY OF 867 CASES SEEN DURING 1948-55

BY

R. P. MALHOTRA, M.R.C.P.

Professor of Clinical Medicine

AND

N. S. PATHANIA, M.D.

Senior Registrar

(From the Department of Clinical Medicine and Cardiology, Victoria Jubilee Hospital and Medical College, Amritsar, Punjab, India)

In a few years' time two centuries will have passed since Heberden described the syndrome of angina pectoris, yet the aetiology of coronary heart disease remains undetermined. Western writers seem to believe that the so-called "material civilization" of the West is responsible for the increased incidence of this disease in their countries and that Asiatics are far less prone to fall victim to this malady. Arnott (1954) says: "Coronary heart disease is one of the main causes of disability and death in the United States, Canada, Britain, Northern Europe, Australia, and New Zealand, and these are all countries which, nationally speaking, derive more than 30% of the food calories from fat. On the other hand, areas like southern Europe, Africa, India, and the Orient in general have diets the fat of which contributes less, usually much less, than 20% of the calories. It is difficult to be certain that atheroma and coronary heart disease are much less in these countries. The extent and standards of medical, biochemical, and pathological work are, generally speaking, much inferior, while the vital statistics of the populations at risk are less clearly defined. Nevertheless, while the evidence is not of the same quality as in the materially more favoured countries, it is uniformly consistent with the conclusion that the diseases are comparatively very uncommon."

Views in an editorial in the *Lancet* (1955) on the subject of coronary disease are thus expressed; "Beside this we have to set the fact that clinicians with experience in the East have long held that the disease is rarer in Asiatics than in Europeans—to an extent that cannot be wholly explained by the Europeans having longer lives. Support for this opinion comes from pathological studies showing that the inhabitants of the Japanese island of Okinawa have little atheroma or coronary-artery disease. In Africa the post-mortem findings of Higginson and Pepler at Johannesburg indicate that severe atheroma is far less common among the Bantus than in American and European hospitals."

In India, publications on the incidence of coronary diseases have been rather few. In recent years prevalence of coronary disease has been pointed out by some Indian authors (Vakil, 1949, 1954; Malhotra, 1951; Samani, 1956). For the present communication we have collected the data of 867 cases of coronary disease seen by us, so that the readers in other countries may be presented with the available picture of this disease in India.

The presented data go to show that coronary disease forms a big group in the cardiac population of this part

of India, and, whereas several of the aetiological factors observed run true to descriptions by Western authors, there are some local factors that may provide material for further thought.

Clinical Material

The series consists of 867 cases of coronary disease that occurred during a period of seven years (1948-55) amongst a total of 3,054 cardiac patients seen by us. These cases, shown in Table I, include patients admitted to general and private wards as well as those examined in the cardiology clinic. Private cases seen in his consulting-room by the senior author (R. P. M.) are also included. Thus it is a fair cross-section of all classes of patients.

TABLE I.—Distribution of Cases Into Hospital and Private Classes

	Males	Females	Total
Hospital class	511	95	606
Private	243	18	261
Total	754	113	867

TABLE II.—Age at Presentation

Females	0	5	21	41	37	7	2	113
Total	3	36	143	341	223	109	12	867

TABLE III.—Age at Time of Onset of Symptoms

	Uncertain	Below 30	30-39	40-49	50-59	60-69	70-79	80+	Total
Males	2	5	53	193	300	138	55	8	754
Females	0	1	6	31	50	18	7	0	113
Total	2	6	59	224	350	156	62	8	867

Age.—As seen in Tables II and III the maximum incidence of the disease is in the 50-59 age group. This age group is the same as that reported by Friedberg (1950) from America, but is one decade younger than the 60-70 age group reported by other Western authors (Parkinson and Bedford (1928) from England, Levine and Brown (1929) from America, and Cassidy (1946) from England). In India Vakil (1949, 1954) reported the maximum incidence between 40 and 50 years, a group one decade younger than our group. In recent years cardiologists as well as general physicians have become fully aware of the occurrence of coronary disease in the young, and this is true of Indian patients as well. Table III shows that 7.5% of cases got their disease before the age of 40. In an earlier community study an incidence of 7% amongst the younger age group was reported (Wig and Malhotra, 1951). Vakil (1949), from Bombay, reported 41 cases (16% of his 250 patients)—a much higher percentage than ours.

Sex.—There were 754 males and 113 females in our series. It is a well-recognized fact that in the West females suffer much less than males from coronary disease. The exact cause of this comparative feminine immunity remains undetermined. Sex ratios varying between 4.2 to 1 and 6.6 to 1 have been mentioned by different Western workers (Clawson, 1941; Bland and White, 1941; Parkinson and Bedford, 1928). In our series the ratio is 6.7 to 1. It may be of some interest to mention that in India women lead a comparatively much more sheltered and indoor type of life, their main occupation being household work, yet the ratio between males and females so far as the incidence of coronary disease is concerned is more or less the same as seen in countries where women rub shoulders with men in all walks of life.

Social and Economic Status

The patients were divided into three classes according to their socio-economic status. The upper class included patients from well-to-do and professional classes such as business magnates, lawyers, doctors, engineers, landlords, or high-salaried Government officials. Their income levels were over Rs. 500 a month. The middle class included people with income levels between Rs. 100 and 500 a month—for example, clerks, schoolteachers, shopkeepers, or middle-class farmers. People with income levels below Rs. 100 per month, such as labourers, factory workers, poor farmers, small shopkeepers, etc., were classified as poor. The females were classified according to the economic status of the family.

Table IV shows that about 91% of the cases came from the upper and middle classes. One cannot draw any conclusion, for the obvious reason that upper and middle classes are more enlightened to seek medical advice readily.

TABLE IV.—Classification of Cases According to Socio-economic Status

	Upper	Middle	Lower	Total
Males	114	573	67	754
Females	6	95	12	113
Total	120	668	79	867

Occupation.—It is believed that professional classes who lead a "chair-borne life" show a higher incidence of coronary disease than those who earn their living by hard physical work (Stocks, 1951; Morris *et al.*, 1953). We classified our patients into three main groups according to the physical activity involved in a particular job. This is shown in Table V. It may be of interest to mention that people who had to earn their living by hard physical

TABLE V.—Distribution of Patients According to Physical Activity Involved in Their Profession

	Sedentary	Average	Hard	Total
Males	425	292	37	754
Females	11	102	0	113
Total	436	394	37	867

activity formed a negligible proportion in this series (4.3%). But these people were mostly poor, and were less likely to seek medical advice readily.

Urban Versus Rural Distribution of Patients

Of the 867 cases, 123 came from rural areas and 744 from towns and cities. Table VI shows their distribution.

In spite of the fact that patients from rural areas formed a mere 14% of our series we cannot conclude for certain that the disease is less prevalent in people belonging to places remote from modern civilization. Patients from

TABLE VI.—Rural and Urban Distribution of Patients

	Rural	Urban	Total
Males	105	649	754
Females	18	95	113
Total	123	744	867

villages come to the town hospitals only when they are severely disabled with congestive heart failure or when their physical activity is seriously curtailed owing to severe effort angina. Brief or mild episodes of coronary disease remain unnoticed. The same is true of sudden deaths. It would be worth while finding out whether the disease is really less common among people who live away from modern civilization. There are areas in this country where the mode of life continues to be what it was in the

contact with the tumour projecting between two papillary muscles. On trial, it was quite easy to push the tumour upwards a short distance. The index finger of the other (left) hand was then put into the atrium by releasing the clamp in the usual way, and the finger-nail was pushed into the tumour pedicle. This separated fairly easily and smoothly from the interatrial wall, while the ventricular or right finger pushed the tumour upwards. Withdrawal of the left index enabled the right finger to push the tumour upwards and into the hole in the left auricle, acting as a cork from inside. The auricular hole had to be enlarged by about 2 cm. with the nail of the left index finger. The tumour popped out of the hole like a cork, followed by a small gush of blood. The assistant, standing ready with the auricular clamp, grasped the auricle at the first attempt, and little blood was lost. A more dignified exit could easily have been made if the tumour had been pushed less forcefully. The auricle was then closed with a continuous suture by the assistant. The right index was removed from the ventricle while the purse-string was tightened: there was no blood loss from this. During the separation of the mass the carotids were compressed in the neck by the anaesthetist.

While the auricle was being closed the opportunity was taken to feel the mitral valve cusps from below, and no nodules or other abnormalities were found. The heart beat continued regular throughout, and only a slight weakening occurred after the sudden blood loss. The wall of the ventricle was normally thick, and showed no sign of hypertrophy or dilatation.

Post-operative recovery was peaceful for the first 10 days: the patient got up on the third day and was discharged on the ninth day. Two days later, however, she had a right pulmonary embolus associated with pain in the left calf and was readmitted to hospital. After 13 days of anticoagulant treatment she was discharged and no complication has since occurred. In December the heart sounds were normal and have not changed since then. When seen 18 months later she was completely well, and had regained her exercise tolerance and lost all other symptoms. The heart sounds were normal, the heart looked normal on radiology, and the left atrium had shrunk to a normal size. The E.C.G. showed a Q wave in lead I and an inverted T wave in leads V5 and V6.

The specimen was an egg-shaped mass measuring 6 by 5 by 4 cm. It was shiny and smooth, with a rough area at its upper end, 2 cm. in diameter, where it had been detached. On section it was grey and semi-translucent, with darker areas of old haemorrhage.

Histology showed an amorphous mucoid matrix with a few stellate cells with spindle-like processes. There were a few elastic and muscle fibres in the mass, and a few developing capillaries. The surface was endothelial, covering a fibrous layer continuous over the whole tumour. There were some areas of old haemorrhage.

Comment

In reviewing the operation, certain points arise. The direction of approach—from the front of the patient (who was lying on her right side)—happens to be L.F.'s usual stance, and was the easier in this case: the right index finger in the left ventricle and the left finger in the auricle allowed a clear view for the assistant, standing behind the patient, to place the auricular clamp with his left hand from behind forwards, towards the pulmonary artery. If the surgeon were to stand behind the patient, and had to put his left index in the ventricle and his right in the auricle, the assistant would be hampered in putting on the clamp. During such an operation the surgeon should, if necessary, change position and place himself in front of the patient.

The myxoma is always larger than the index finger, since it is large enough to obstruct the mitral valve and produce symptoms; the auricular hole will therefore always be closed when the tumour has been jammed into it, and when the

left index is removed no bleeding will occur. The hole will need enlarging to allow removal of the mass. The enlargement should be done in the direction in which it is easier to apply the clamp, and this is probably backwards, above and parallel to the AV groove, and about $\frac{1}{2}$ in. (1.3 cm.) away from it. The hole should be enlarged gradually, until it is seen to be just big enough to let the tumour squeeze through: the purse-string should be opened as required to allow space for the incision, or, if no purse-string is used, the edges can be caught with forceps. The tumour is pushed out either by the internal finger or by squeezing it out gently with the clamp, or both. The inside finger should not be removed until there is no further danger of the tumour slipping back or of breaking.

Extraction is done slowly, and the intraventricular finger can judge when the incision is large enough by exerting gentle pressure *a tergo*: it can be kept between the mitral cusps as long as is necessary, since it will always be smaller than the valve orifice, which usually takes two fingers and has, in any case, been occupied by the tumour. The outside hand can prevent a too sudden explosive ejection of the tumour and may itself grip the edges of the auricular hole and partly or entirely close it. If the procedure is done slowly and gently, fragments will not be torn off and the carotids need not be compressed for a longer time than is needed to detach the tumour from the inter-auricular septum.

In our case the mass was easily cut off the inter-auricular septum by the gloved finger-nail; if the pedicle had been too tough for this, Brock's valvotomy knife would have served the purpose. The septum was left smooth and normally elastic, and gave no impression of there being a tumour growing from the septum.

Discussion

The gross physical characters of the myxoma are fairly constant in essentials, the appearance, size, and shape being due to moulding and compression of the tumour by the heart muscle, and by the mitral valve, which it accurately fits. In fact, in all the cases described, the tumour is large enough and of such shape as to obstruct the blood flow and almost to fill the left atrium, whatever its size. This is beautifully shown in the angiocardiograms of Goldberg *et al.* (1952) and Goldberg and Steinberg (1955), in which two hearts are shown, containing myxomata, one of them twice the size of the other.

The tumour is smooth, shiny, roughly egg-shaped, lobulated at its lower end, and in reported cases measures from 10 by 6 by 4.5 cm. (Mahaim, 1945a) to 4 by 4 by 2 cm.: a

Two views of myxoma removed at operation, split and folded open. The site of attachment is clearly seen.

number of small non-occlusive ones have been found by chance. Its upper end is attached to the atrial septum above the postero-medial end of the anterior mitral cusp, about the site of the foramen ovale. It hangs through the mitral orifice into the left ventricle, impinging on the musculi papillares and the ventricular wall; its lobulations correspond to the irregularities of this contact. It occurs much less commonly on the right side of the heart, attached at the same place, on the fossa ovalis; it has never been described as occurring in both auricles at once, nor has a projection been seen through the atrial septum; and perforation of the septum by tumour is unknown.

Opinions differ whether the mass is a myxoma or an organized clot, but we are not discussing the controversial problem of its origin. It is covered with endothelium and a subendothelial fibrous layer, both continuous with the surface layers of the atrial wall. Van Buchem and Eerland (1957), in a case diagnosed and treated by them, say that the "pedicle was easily detached from the septum," and that at necropsy "the site of the myxoma was only indicated"; both facts suggest that we are not dealing with a true growth of the septum. A number of surgeons have cause to regret the ease with which the tumour can be detached. No other simple tumour has such a frail pedicle. In the present case however, the pedicle was firm.

When the tumour has grown to over 3 cm. in diameter pieces may break off and form emboli in the brain (Mills and Philpott, 1951), aorta (Likoff *et al.*, 1954), spleen, etc. The histological appearance of the embolus is characteristic enough to be identified with certainty. Even to the naked eye the grey semi-translucent jelly with a smooth surface is so different from the rough brown surface of the ordinary blood clot that the origin of the embolus can be immediately recognized. Embolism is relatively common, and may be large, blocking the aortic bifurcation: in true mitral stenosis an embolus that can get through the narrow orifice is very unlikely to block the aorta. Sudden enlargement of the tumour by bleeding into its substance may precipitate obstruction and pulmonary oedema or a severe "peripheral arterial syndrome" with gangrene of the toes, fingers, nose, etc. (Mahaim, 1945a).

The consistency of the myxoma is usually described as "rubbery" and fairly soft; in the present case the finger could be pushed into it if moderate force was used, but it was elastic enough not to break up or to form fragments.

Signs and Symptoms

Myxomata have been found in patients of all ages between 3½ and 68 years, and of both sexes. In some cases the history has been a relatively short one, and this may be a useful though not decisive point in the distinction from mitral stenosis. In one of Goldberg and Steinberg's (1955) cases there was a history of 23 years.

Other symptoms are those of mitral stenosis—namely, dyspnoea on effort, tiredness, nocturnal dyspnoea, haemoptysis, syncopal attacks, peripheral arterial syndrome (Desbaillets *et al.*, 1953).

The signs are those of mitral stenosis: much has been made of the fact that they are variable, sometimes being those of mitral incompetence and at other times of mitral stenosis. This variability has been particularly associated with posture, but this association has not been clearly defined in most of the reported cases: it would be expected that on lying on the back signs of mitral incompetence would be produced, and on leaning forward those of mitral stenosis. In hardly any of the reported cases has this been emphasized; but Mahaim (1945b) mentions two patients in whom a systolic murmur appeared, one in decubitus and the other on sitting up. In the first patient a pre-systolic murmur appeared on sitting up. Further, it must be remembered that in true mitral stenosis the signs are sometimes variable at different times and in different positions, and especially variable is the systolic murmur. This systolic murmur is sometimes attributable to tricuspid incompetence.

A point to remember is that the axis of the mitral valve, and the direction of the blood flow from the left auricle to the left ventricle, are forward and only slightly downwards, and certainly not in line with the axis of the trunk. With the patient lying on his back the blood stream and the tumour are pointing very nearly straight upwards. A blood flow even as low as 2 litres a minute would make it very unlikely that the tumour could slip back against it, even when aided by gravity.

It is possible, however, that each ventricular systole might push the mass backwards into the atrium, and the tumour may even allow a certain amount of regurgitation of blood by preventing the cusps from closing properly (Zinsser and Johnson, 1953). This may account for the appearance of strong systolic pulsation seen against the oesophagus by van Buchem and Eerland, and considered by them to be strongly suggestive of the diagnosis. Paradoxical pulsation has otherwise been discredited both as a positive sign of mitral regurgitation and as a negative one against mitral stenosis.

Seven pre-operative diagnoses have been made (Goldberg *et al.*, 1952; Zinsser and Johnson, 1953; Goldberg and Steinberg, 1955; Soboff and Zatzuchni, 1956) by means of angiocardiology, and no doubt this method will discover many more. But it has not usually been clear on what grounds angiocardiology has been recommended. We have tried to point out the fallacies in all the diagnostic points, and suggest that many cases will occur in which angiocardiology has not been done and the surgeon will be surprised. Goldberg and Steinberg (1955) give four indications for angiocardiology: (1) signs of mitral stenosis not dating from birth in young children; (2) absence of cardiac difficulties until the onset of intractable heart failure; (3) inconstancy of mitral murmurs; and (4) episodes of syncope or cyanosis on change of position. These four points are of value, but certainly the third and fourth are misleading. However, as angiocardiology becomes easier and more reliable (Soboff and Zatzuchni, 1956), myxomata will no doubt be discovered more often, and differentiated from mural and ball thrombi.

In 1952 Goldberg *et al.* described the case of a child aged 3½ in whom the tumour was diagnosed by angiocardiology; at operation the heart stopped before the pericardium was opened. The auricle was incised and the tumour removed by spoon and pituitary rongeur. The heart action was started again, but lasted only a few hours.

Crafoord operated successfully on a patient by means of the extracorporeal pump and oxygenator, as reported by van Buchem and Eerland (1957). The tumour was the size of a "small orange."

Brock (1956) has proposed and practised the approach to the myxoma through the right auricle, excising a circle of interatrial wall with the tumour pedicle, pulling out the tumour and stitching up the hole, with an arrested circulation under hypothermia. Eerland, also using hypothermia, removed a myxoma by making an incision in the left atrium as well as in the left auricle, and pushing the tumour in the atrial hole. After dividing the pedicle "the tumour was kept floating and pressed against the site where the left atrium was to be incised. The latter procedure was performed with the left hand. . . ." In both Brock's and Eerland's cases the patients succumbed to the complications of hypothermia. Chin and Ross (1957) succeeded in one case by carrying out Brock's suggestion, again under hypothermia. A few other cases of unsuccessful operative removal of myxoma of the left atrium have been reported (Goldberg *et al.*, 1952; Clowes *et al.*, 1954; Brock, 1956).

Ventricular cardiectomy produces ventricular fibrillation more easily than does the auricular approach; but it must be added that this danger is related to ventricular hypertrophy, fibrosis, and ischaemia, and a normal or thin ventricular wall carries little risk. The approach to the mitral valve through the ventricle is used by Logan (personal communication) in cases of difficulty in performing mitral

valvotomy, and he finds it satisfactory. In the present case, as in all cases of mitral obstruction, the muscle was normal and produced only an occasional extrasystole when cut and stretched.

When the tumour is discovered during a mitral valvotomy, one alternative treatment is to stop the operation and repeat it later with the help of hypothermia or cardiac bypass. In one such case the patient died two days after the first operation (Jones and Julian, 1955). Another alternative is to start immediately with hypothermia, but this involves considerable reorganization, whichever method of cooling is to be used. The third alternative is proposed in this paper.

Summary

A case of successful excision of an atrial myxoma is described.

It is shown that the symptoms and signs are almost indistinguishable from those of mitral stenosis, and that most cases will be discovered unexpectedly during the course of mitral valvotomy.

A simple method of dealing with the situation is described: this avoids having to abandon the operation with the intention of performing open cardiectomy later, under hypothermia or with the cardiopulmonary bypass. Abandoning the operation is in itself a danger; and open cardiectomy is less safe than the operation described.

The method consists of pushing up the myxoma with a finger through a small hole near the tip of the left ventricle; at the same time the index finger of the other hand, through a hole in the atrium, divides its pedicle, and guides it towards the auricular hole. While it is pushed through the hole it acts as a cork, and the auricle is clamped behind it as it falls out.

It is pointed out that the left ventricle in all cases of mitral obstruction is not hypertrophied or ischaemic, and an incision into it carries little risk.

We thank Dr. Wagner, who discussed the histology and aetiology; the South African Institute for Medical Research (Pneumoconiosis Research Unit) for the photographic reproductions; and Mr. Crawshaw, assistant to one of us (L. F.).

Following the reorganization in 1955 of the Bexleyheath club for mentally handicapped children into an independent club for children with any type of mental or physical handicap, a committee for youth clubs for the handicapped was set up in 1956 to promote other similar clubs. By January this year a chain of clubs was formed in north Kent, and 17 new clubs had opened in London and the south-eastern counties. The campaign has now spread to four other counties, nine new clubs have opened, and 17 districts are organizing facilities. These clubs aim to socialize and educate handicapped children and give parents an opportunity of regular contact, and to dispel misconceptions and old wives' tales by acting as a focal point of local interest in mental handicap. The Bexleyheath club has 23 members, age range being 10-33 years, with mental ages of 3-9.

CHRONIC MIDGUT ISCHAEMIA

BY

G. E. MAVOR, M.D., Ch.M., F.R.C.S.Ed.

AND

Wm. MICHIE, F.R.C.S.Ed.

Aberdeen Royal Infirmary

Arterial thrombosis secondary to atherosclerosis is initially of limited extent. The surgical exploitation of this pathological finding is now accepted as justifiable, and direct surgical treatment by thrombo-endarterectomy or by the insertion of a graft, either as a replacement or as a shunt, gives better results than any other form of palliative therapy (Martin and Gaylis, 1957; Mavor, 1957). In most cases the atherosclerotic occlusions so treated have been in the aorta, its terminal branches, and the lower-limb arteries (Rob, Eastcott, and Owen, 1956; Martin and Gaylis, 1957). More recently it has been shown that atheromatous narrowing of the internal carotid artery can be successfully dealt with by direct surgery, and the ischaemic cerebral symptoms relieved (Rob and Wheeler, 1957).

Similar opportunities for surgery may exist in relation to the superior mesenteric artery, where for a time severe narrowing or local thrombosis may precede more extensive occlusion and infarction of the bowel. Although the symptoms resulting from such chronic midgut ischaemia have been described previously (Klein, 1921), their treatment by direct surgery on the superior mesenteric artery is now more apparently feasible. Accordingly it appears justifiable to recall the clinical picture and describe two recent cases.

Case 1

A man aged 49 was first seen because of lower abdominal pain. Four months previously he had a sudden onset of severe lower abdominal pain. This was associated with vomiting, and the next day he passed three or four dark fluid stools. The severity of the pain subsided after several days, but some pain remained present daily. This pain, situated in the lower abdomen, was continuous in nature and aggravated by a heavy meal, particularly of meats or fats. He had no abdominal colic, no night pain, and no back pain. Occasionally after a large meal he vomited. During this period he tended to be constipated, but since the original episode had had two episodes of diarrhoea, each lasting a few days. His appetite was poor and he lost 21 lb. (9.5 kg.) in weight in four months.

On examination he was a thin man of good colour. There were no findings of significance in the abdomen. Rectal examination was negative. Stool benzidine examination was positive. Haemoglobin was 92%, and a barium-meal and follow-through examination showed no abnormality.

He was seen twice during the next three months. Diarrhoea had become more persistent and he passed two or three stools daily. These were watery but well coloured. The abdominal pain persisted, being present every day. There was no further vomiting. Weight loss continued, the total loss over seven months being 35 lb. (15.9 kg.). On one occasion rectal examination revealed soft yellowish faeces which suggested fat malabsorption. Fatty acids were present on examination. Stool benzidine examination continued to be positive, and a further haemoglobin estimation was 90%. Barium enema showed no abnormality.

Seven months after the onset of symptoms and while awaiting admission to hospital for investigation, he entered as an emergency case, complaining of severe abdominal

pain. For the previous six days he had constant lower abdominal pain of great severity. He vomited brownish material several times. He had had no adequate bowel movement over the previous five days, although he had passed some dark fluid faeces from time to time. The abdominal pain and vomiting had increased over the previous 24 hours, and abdominal distension had become apparent.

On examination he was emaciated and suffering severe pain. The blood pressure was 160/100 mm. Hg, and the pulse rate 90 a minute. His extremities were cold, there was peripheral cyanosis, and venous filling was poor. Other significant findings were restricted to the abdomen, which was distended. There was slight lower abdominal tenderness, but no rigidity and no palpable mass. The abdomen was tympanitic on percussion and quiet, with occasional high-pitched bowel sounds on auscultation. The bladder was not distended and the rectum was empty.

The patient was given 10,000 units of heparin and intravenous therapy was begun. A Ryle tube was passed and 120 ml. of dark-brown fluid aspirated from the stomach. At laparotomy the small bowel (excluding the duodenum), caecum, and ascending colon were gangrenous. Peritonitis was well established. There was no pulsation in the superior mesenteric artery, which appeared thrombosed from its origin. No definitive surgical procedure was undertaken. The patient died eight hours later.

Post-mortem Findings.—The only abnormal findings were related to the abdomen. The peritoneal cavity contained a small amount of blood-stained serous fluid, and the entire small bowel and proximal half or thereby of the large bowel were necrotic. This extensive infarction of the bowel was due to thrombosis occluding the orifice of the superior mesenteric artery. In addition to the recent thrombus at the orifice, there was just inside the orifice an older organized layer of thrombus which was partly occluding the

FIG. 1.—Case 1. Section through superior mesenteric artery showing lumen just distal to origin narrowed by atheroma and occluded by fresh thrombus.

FIG. 2.—Case 1. Section showing wall of atheromatous superior mesenteric artery and lumen containing unorganized thrombus. (×32.)

vessel wall (Figs. 1 and 2). Beyond this the artery was free of atheroma and contained only post-mortem clot. The abdominal aorta was healthy.

Case 2

A man aged 46 had suffered from abdominal pain for the previous nine weeks. This pain was of sudden onset. It was very severe, was felt in the epigastrium, was unrelated to meals, and was associated with nausea and vomiting. It persisted in severity over several days, along with nausea and vomiting. The vomit was never obviously brownish or blood-stained. Anorexia was complete, largely owing to the intractable nausea. Diarrhoea was present, the stools being watery and well coloured.

Over several weeks the epigastric pain became less severe, although it was often worse after meals. The faeces became progressively lighter in colour and the diarrhoea persisted, becoming, along with abdominal pain, his main complaint.

Two weeks before admission to hospital some improvement had occurred in his condition. Abdominal pain, although present each day, was much less severe, and there was no further vomiting. Diarrhoea, however, was still present, and weight loss had continued, reaching 49 lb. (22.2 kg.) over the nine-weeks period.

His past history revealed symptoms of duodenal ulcer lasting 21 years. About a year previously a partial gastrectomy had been carried out. For some months after this operation he had postprandial umbilical discomfort following large meals, occasionally associated with eructations and diarrhoea. During the week prior to admission to hospital he developed a fissure-in-ano.

On examination he showed evidence of recent weight loss. Blood pressure was 130/90 mm. Hg and pulse rate 78. There were no significant findings on examination. The abdomen showed no abnormality apart from a right paramedian scar.

The following investigations were undertaken. Blood picture: haemoglobin, 97%; white cells 8,000 (normal differential); platelets, plentiful; red cells, normal; E.S.R., 17 mm. per hour. Urine: no abnormality. Stool: culture negative; undigested fat globules, and a considerable excess of fatty acids; benzidine-positive. Blood urea, 38 mg./100 ml.; serum alkaline phosphatase, 24 units; serum bilirubin, less than 0.2 mg./100 ml.; plasma proteins, 6.56 g./100 ml.; serum amylase, 200 mg./100 ml.; thymol turbidity, 3 units. X-ray examination of chest, negative; cholecystogram, negative; barium enema, negative; barium-meal examination: gastrectomy evident, normally functioning stoma, and no evidence of anastomotic ulcer; some tendency to delay in emptying of proximal jejunum. In view of the excess fat in his stool a fat-balance test was attempted, but had to be discontinued because of intense pain due to his fissure-in-ano.

During this period in hospital his general condition improved. The abdominal pain subsided, although he continued to have diarrhoea and pass rather pale and greasy-looking stools. His main complaint was related to his anal fissure. This was injected with some relief.

After five weeks in hospital he was sent home with a view to being readmitted for fat-balance studies. While at home his condition remained unchanged. He felt unwell and weak, and suffered umbilical and lower abdominal pain almost daily. This was often severe—a constant grinding pain which did not radiate. It was made worse by meals, so much so that he often refused to eat. There was no vomiting. Diarrhoea persisted, several stools being passed each day. The consistency of the stool was fatty and "undigested-looking"—pale, greasy, and floating on the surface of the water. He lost a further 10 lb. (4.5 kg.) in weight.

Seven weeks after discharge he was readmitted to hospital. There were no significant findings on examination except that the left femoral pulse was noted to be weaker than the

Methods and Treatment

Clinical.—All the patients were males within the 19–30 age group. They were seen before admission, when a history was taken and a physical examination made. A throat swab was taken at the same time. Thereafter patients were examined daily by one of us (P. J. T.), when each patient was asked whether or not his throat felt sore and his answer recorded. The degree of injection, oedema, and exudate was noted. Oral temperatures were taken at four-hourly intervals until the temperature had been normal for 24 hours, and thereafter twice daily. The clinical criteria for discharge were symptom-free, afebrile, and a clean throat. A throat swab was then taken, and the patient left hospital next morning provided that no haemolytic streptococci had grown overnight. If this organism was found the patient was retained in hospital and given a three-day course of phenoxymethylpenicillin regardless of his previous treatment. No patient was allowed to leave hospital until his throat swab had been found clear. Two further throat swabs were taken at weekly intervals, and on all these three occasions urine was tested for proteinuria.

Cases were treated by one of three methods on a non-selective basis for a minimum of three to four days: (1) soluble aspirin tablets, 10 gr. (0.65 g.) four-hourly in 40 cases; (2) sulphatriad tablets, 4 g. stat. and 1.5 g. four-hourly in 37 cases; (3) phenoxymethylpenicillin tablets, 120 mg. eight-hourly in 39 cases. Patients in the last two groups also received soluble aspirin. All patients remained in bed until their temperature had been normal for 24 hours. Patients were allocated into treatment groups alternately, depending solely upon the order in which they were admitted to hospital—an administrative list beyond our control.

Results

Clinical features were very similar to those noted in our previous paper and in other descriptions of the illness. Those patients admitted on the first two days were more ill than those admitted on subsequent days. Injection of the throat was seen in every case, together with a variable amount of oedema. Exudates were seen in those with tonsillar tissue. 17 had a temperature of 99° F. (37.2° C.) or less, although they had a sore throat. Four others did not complain of sore throat. Scarlet fever developed in 31 cases (see Table).

Laboratory Findings.—Every patient had a throat swab taken on admission, and 65 (56%) were found to carry *Streptococcus pyogenes*. Of seven cultures sent to the Streptococcal Reference Laboratory, four were Lancefield group A and three were group G.

Comparison of Treatment Groups.—108 patients were admitted to the trial having had the unselective course of treatment without amendment until they were clinically fit for discharge from hospital. No distinction is made between those with positive or negative throat swabs on admission. This is because the outbreak showed all the characteristics of a food-borne infection and there was no clinical difference between the two groups: aspirin, 35 cases; sulphatriad, 35 cases; phenoxymethylpenicillin, 38 cases.

Of the many methods available for assessing the efficiency of treatment we have selected four: duration of "soreness" of the throat, duration of fever, length of stay in hospital, and the carrier rate.

Duration of "Soreness" of the Throat.—The answers received from daily questioning of patients are shown in Fig. 1; it is clear that there was no difference between the three groups.

Duration of Fever.—Fig. 2 shows that there was no difference between sulphonamides and aspirin, while penicillin showed a slight difference on the third day only, although it is not statistically significant (difference/standard error=1.6).

FIG. 1.—Duration of sore throat. Aspirin,; sulpha, ----; penicillin, ———.

FIG. 2.—Duration of fever. Aspirin,; sulpha, ----; penicillin, ———.

FIG. 3.—Days in hospital to clinical discharge. Aspirin,; sulpha, ----; penicillin, ———.

Length of Stay in Hospital.—In the present epidemic, when patients with a positive throat swab were kept in for a further three days, this figure is dependent upon two factors: clinical recovery and bacteriological normality. The latter factor depends on the carrier rate of the treatment concerned, and Fig. 3 represents the time taken for clinical recovery alone. Here again there was no difference between the sulphonamide and aspirin groups. Those patients treated with penicillin, however, showed a tendency to recover more quickly, but this did not become significant until the seventh day (difference/standard error=2.15).

Positive Throat Swabs following Treatment.—Only 10 patients were found to have a positive throat swab after clinical recovery: penicillin, 1 case (2.6%); sulphatriad, 1 case (2.8%); aspirin, 8 cases (22.8%). The difference here is self-evident. The overall carrier rate two weeks after discharge was 6.9%.

Complications.—No cases of rheumatic fever or acute nephritis were discovered. Two cases of mild otitis media as evinced by injection of the tympanic membrane were discovered on admission, but these had settled by the next day. Two patients had brisk diarrhoea lasting one day only, and examination of stools did not indicate dysentery.

Discussion

The present trial has shown that neither sulphatriad nor oral penicillin reduced the duration of soreness of the throat. The only positive finding was the fact that they both reduced the number of positive throat swabs following treatment. In what is perhaps the most important assessment—namely, the duration of the illness as a whole—the results showed only a slight but significant reduction with the use of oral penicillin. The duration of fever was slightly less in those patients on penicillin, although the difference was not statistically significant.

The length of the illness is usually the resultant of three factors: cessation of fever, the disappearance of pain, and, in all patients under medical supervision, a reasonably normal appearance of the throat. We have shown that the first two factors are independent of treatment. It is well recognized that, in cases of sore throat, people with tonsils have more visible exudate. It has also been shown that the more visible exudate is associated with a higher re-presentation of tonsillar tissue (Bloomfield and Felty, 1923; Taylor and McDonald, 1958).

Penicillin kills the pathogens more quickly than symptomatic treatment, thereby hastening the recovery of the throat to a normal appearance, thus shortening the illness.

It has been claimed that a further indication of the value of a given treatment may be obtained from an examination of its more obvious failures (Chapple *et al.*, 1956). Of the eight patients who were taken out of the trial because their treatment had been altered, five had received aspirin alone, two sulphonamides, and one penicillin. While this may seem to suggest that aspirin was the least effective form of treatment, this is not necessarily the correct conclusion.

The results of previous trials suggest that there seems to be little difference in the symptomatic effects of penicillin whether the infection is considered to be streptococcal or not (Chapple *et al.*, 1956).

It may well be that tonsillitis is often a double infection of viruses and bacteria. This may be the reason why penicillin has no strikingly beneficial effect in the treatment of tonsillitis.

Summary

A food-borne epidemic of 116 cases of streptococcal tonsillitis, including 31 cases of scarlet fever, is described.

A controlled trial using sulphonamides and oral phenoxymethylpenicillin is presented.

The results suggest that oral penicillin has no beneficial effect on the soreness of the throat but speeds the recovery of the normal appearance of the throat, the lowering of temperature, and the duration of illness.

We thank the Director-General of the Royal Air Force Medical Services for permission to publish. We also thank Dr. R. E. O. Williams, of the Streptococcus Reference Laboratory, and Dr. J. C. McDonald, of the Public Health Laboratory Service, for helpful advice and criticism in the compilation of the paper.

F. VELLA, M.D.

Department of Biochemistry, University of Malaya, Singapore

In a survey of blood used for transfusion in Singapore it was noted that the blood of a young Englishman contained two haemoglobins, one with the electrophoretic properties of haemoglobin A and one other, amounting to 27%, which was moving faster than A on paper electrophoresis using barbiturate buffer of pH 8.6. By comparison with eight AJ specimens—one from Africa (Dr. J. Stijns), three from Indians (Dr. A. B. Raper; Dr. L. D. Sanghvi, and Mr. P. K. Sukumaran), one from Indonesia (Dr. Lie-Injo Luan Eng), and three from Chinese in Singapore—it was established that the electrophoretic mobility of the fast component on paper at pH 8.6 was similar to, although slightly faster than, that of haemoglobin J.

There was no haematological or clinical abnormality. When the young man's immediate family in England was examined it was found that his mother possessed only haemoglobin A, and that his father and his younger brother were also carriers of this new haemoglobin variant in the same proportion. The family is of Norfolk farming stock and so far as they are aware they are purely English. Thus this is the first observation in an English family of an abnormal haemoglobin. Neither the father nor the brother of the propositus was anaemic, and a full haematological investigation of the father yielded normal values only; in particular there were no target cells and no abnormal osmotic fragility; the haemoglobin A₂ fraction was not increased.

Investigation of the New Haemoglobin

The new variant from the Norfolk family was only just distinguishable from haemoglobin J on paper electrophoresis at alkaline pH—moving slightly faster (Fig. 1). However, whereas haemoglobins A and J do not separate on chromato-

graphy (Huisman and Prins, 1955), there was a distinct separation between A and the present haemoglobin by this technique (Fig. 2). Huisman, Noordhoek, and da Costa (1957) stressed their inability to separate haemoglobins A

Fig. 1.—Filter paper electrophoresis, pH 8.6. Haemoglobin "Norfolk" moves similarly to, but slightly faster than, haemoglobin J.

and J, using a range of buffers from pH 5.7 to pH 8.5 of widely varying concentrations. It could be argued that the new haemoglobin is only a minor variation of haemoglobin J. However, if the routine method of investigating haemoglobins was that of column chromatography and not paper electrophoresis a similar argument could be raised against differentiating haemoglobins J and K, which do not separate on chromatography but differ on paper electrophoresis at alkaline pH.

Haemoglobins A and J do not separate on paper electrophoresis at pH 6.5 or pH 7 (cacodylate buffer). The present haemoglobin showed some slight spreading under these conditions, though there was no perfect separation. There was no separation at all on starch electrophoresis at pH 6 (citrate buffer) (Fig. 3). There was no denaturation when the haemoglobin was kept frozen for several months, and when it was treated with alkali (Singer, Chernoff, and Singer, 1951) it was fully denatured. The solubility of the ferrohaemoglobin in Itano's (1953) test was 1.7 g./litre of 2.58 M phosphate buffer. The visible and ultra-violet spectra of the carboxyhaemoglobin were identical with those of haemoglobin A.

Summary of Properties of the New Haemoglobin.—(1) Moving slightly faster than J and considerably more slowly than "Bart's" and N on paper electrophoresis at pH 8.6 (barbiturate buffer). (2) Showing some slight separation on paper electrophoresis at pH 6.5 and pH 7 (cacodylate buffer). (3) Not separating from haemoglobin A on starch electrophoresis at pH 6 (citrate buffer). (4) Separating from haemoglobin A on column chromatography on "amberlite IRC-50" at pH 6 (citrate buffer). (5) Being denatured in the conventional test for alkali resistance. (6) Being resistant to cold denaturation. (7) Having the same carboxyhaemoglobin spectrum in visible and ultra-violet light as haemoglobin A. (8) Showing in a 27% mixture with haemoglobin A a solubility of 1.7 g./litre in 2.58 M phosphate buffer. (9) Being present in a father and two of his sons. (10) Producing no haematological abnormality in the trait carrier.

Electrophoretically abnormal haemoglobins must be rare in Britain. Matthias (1958) examined 500 unrelated British out-patients at St. Bartholomew's Hospital in London without discovering one abnormal haemoglobin. The propositus

Fig. 3.—Starch electrophoresis, pH 6, of haemoglobins A+N (below) and A+"Norfolk" (above) respectively. N clearly separates and moves behind A at this pH. There is no separation of A and "Norfolk."

is the only one of 2,550 Britons examined in Singapore to show an electrophoretically abnormal haemoglobin—his serial number was 2105.

Naming of the New Haemoglobin

It is becoming increasingly difficult to separate the various haemoglobins by paper electrophoresis, and the application of more than one technique is required for their identification. In 1953 a number of workers interested in abnormal haemoglobins met and proposed that haemoglobins should be designated by letters of the alphabet in order of their discovery (Statement on Hemoglobin Nomenclature, 1953). The proposals of this committee found universal acceptance.

This method of naming new haemoglobins was practicable only so long as they were discovered in small numbers. There soon arose difficulties, however, when different haemoglobins were given the same letter by their discoverers. Thus Cabannes and Buhr (1955) called a new haemoglobin I, a letter which Rucknagel, Page, and Jensen (1955) had used for their haemoglobin which they had originally called H, not realizing that H was the name of a new haemoglobin discovered by Rigas, Koler, and Osgood (1955). Cabannes and his colleagues (1956) next selected the letter J, only to discover that J had been claimed for another haemoglobin by Thorup, Itano, Wheby, and Leavell (1956). The next available letter K was finally adopted.

Recently two different designations have been given to what is almost certainly the same haemoglobin when Ceppellini *et al.* (1958) named a pigment associated with haemoglobin A₂ haemoglobin A₂' and Masri *et al.* (1958) described it as A₄.

One way out of this dilemma was pointed by Robinson, Zuelzer, Neel, Livingstone, and Miller (1956). They provisionally named two haemoglobins after their place of origin, Liberia I and Liberia II, until they were finally identified as haemoglobins N and K respectively. This example has been widely followed.

It is more than likely that the pace of discovery of haemoglobin variants will increase rather than slacken. In the absence of a central organization the allocation of letters by individual research workers risks confusion.

During the last year we were faced three times with the problem of naming a haemoglobin. For the first, haemo-

globin L (Ager and Lehmann, 1957), we wrote to a wide circle of interested research workers and obtained universal approval for the use of this letter. When we wanted to designate the haemoglobin which we called Q (Vella, Wells, Ager, and Lehmann, 1958), we repeated this procedure and had to take into account what we could discover about haemoglobins awaiting designation. We therefore used the letter Q, although at the time of our submitting the paper for publication neither N, O, nor P had yet been publicly allotted. It was obvious that such a way of naming a haemoglobin could not continue, so that when it came to naming an abnormal foetal haemoglobin found in an infant at St. Bartholomew's (Bart's) Hospital in London we followed the example of Robinson and his colleagues (1956) and called the new pigment haemoglobin "Bart's" (Ager and Lehmann, 1958). For the same reason we have now decided to name the present haemoglobin the "Norfolk" type and will leave it to international agreement at a future date to allot a final designation.

An additional complication is that new techniques may demonstrate that haemoglobins thought to be identical by present-day methods are in fact different. Itano (1956) has drawn attention to the contradictory findings from different laboratories on the solubility of haemoglobin C and questioned whether there were not two different haemoglobins both with the electrophoretic properties of haemoglobin C. No fewer than three different haemoglobins have been discovered by comparing the peptides resulting from tryptic digestion of haemoglobins which by the conventional techniques had been identified as D (Benzer, Ingram, and Lehmann, 1958).

Should these haemoglobins now be called haemoglobins D₁, D₂, and D₃, or should only one of them be called D, and if so which, and the other two R and T? If one realizes that the differences between haemoglobins A, S, and C consist as Ingram (1957) and Hunt and Ingram (1958) have shown in there being one different amino-acid in each of some 300 forming the two chains of the globin molecule, and that these differences are due to the action of one single gene, it becomes clear that there is an almost indefinite number of permutations and possible variants of haemoglobins—far outnumbering the letters of the alphabet.

Eventually it will be possible to designate the haemoglobins by their amino-acid sequence, but some *ad hoc* measure for an interim classification will have to be taken. To start the discussion we suggest a scheme which first divides the foetal haemoglobins from the adult variants, these latter being grouped according to their electrophoretic mobilities on paper at pH 8.6. This technique and this pH are the most widely used and separate from haemoglobin A all known adult variants except haemoglobin M. The adult variants could be divided into six groups, depending on their distance from the line of application after electrophoresis. The groups could be named I, II, III, etc., or they could have the name of the first haemoglobin discovered within the group.

Foetal variants

F, "Fessas and Papaspyrou," "Bart's."

Adult variants

- "Slow" haemoglobins:
 - Group I or C group: C, A₂', E-A₂, O.
 - Group II or S group: S-D and variants of D.
 - Group III or G group: L-P, G, Q.
- Group IV or A group: A-M.
- "Fast" haemoglobins:
 - Group V or J group: K, J, "Norfolk," N.
 - Group VI or I group: I, H.

Within each group the haemoglobins could be numbered according to their mobility, or when they have the same mobility they could be given—according to the time of their discovery—the additional letters a, b, c, etc. Thus haemoglobin L, G, and Q would be "G group" 1, 2, and 3 respectively. Since P moves at alkaline paper electrophoresis with the same speed as L, L and P would be respectively

"G group" 1a and "G group" 1b. If after such a scheme was adopted a haemoglobin was discovered which moved, say, between haemoglobins E, A₂, and O ("C group" 3 and "C group" 4), it would then have to be classified as "C group" 3/4. If it was possible to place a haemoglobin between the hypothetical pigment "C group" 3/4 and O ("C group" 4) it could be designated "C group" 3/4/4.

Foetal

F, "Fessas and Papaspyrou," "Bart's"

Adult

Group I or C group	"C group"
C, A ₂ ', E-A ₂ , O	1, 2, 3a, 3b
Group II or S group	"S group"
S-D and its variants	a, b, etc.
Group III or G group	"G group"
L-P, G, Q	1a, 1b, 2, 3
Group IV or A group	"A group"
A-M	a, b
Group V or J group	"J group"
K, J, "Norfolk," N	1, 2, 3, 4
Group VI or I group	"I group"
I-H	a, b

When a new haemoglobin is discovered it can safely be allotted to one of the six groups, but a digit should only be assigned after full comparison and international agreement. It is obvious that it would remain the general practice to refer to the common and well-known haemoglobins by their present names—S, C, D, E, etc.—but the more obscure pigments might well be labelled by giving the group a digit, and, if necessary, with the digit a small letter.

We should like to emphasize that it is not our intention to propose here a new nomenclature or classification of the human haemoglobins, but merely to suggest a scheme which might serve as a basis for discussion. To use these designations without prior wide agreement would confuse rather than clarify the situation.

Summary

A new haemoglobin resembling haemoglobin J but not identical with it is described. It has been found in a purely English family. It is named the "Norfolk" type. The difficulties of naming new haemoglobins are discussed, and a scheme is suggested which might help to avoid confusion.

Our grateful thanks are due to Dr. M. M. H. Gibson Hill, Director, Blood Transfusion Service, General Hospital, Singapore, for her interest and help in providing blood samples from the propositus; and to Mr. V. Price-Jones, of the West Norfolk and King's Lynn General Hospital, for his kind help in obtaining specimens from the family of the propositus.

There is no indication in the literature that *P. ovale* has ever been proved to be responsible for allergic symptoms. Yet here is a fungus to which the skin should have unique opportunities of becoming sensitized. It was determined, therefore, to carry out a systematic survey of allergic patients for evidence of positive skin reactions and clinical responses to this organism.

Skin Testing.—The method of skin testing in use in the clinic is to prick through a drop of the extract at a concentration equivalent to 20,000 Noon units. Most of the

If the 38 patients positive to *P. ovale* are re-examined it is found that half of them have reactions equal to or larger than that of the histamine controls. Table IV analyses their

The rash in the cases with eczema occurred not only on the head and neck but also, in some of them, on the arms, chest, back, and thighs.

Particular care is needed in the selection of shampoos, as several patients in addition to Case 1 have become sensitized to them. Patch testing should always be done before using a fresh preparation and on the first sign of increased irritation.

NYLON HAIR-NET DERMATITIS

BY

C. D. CALNAN, M.B., M.R.C.P.

Dermatologist, St. John's Hospital for Diseases of the Skin
and the Royal Free Hospital, London

R. H. MARTEN, B.M., M.R.C.P.

Dermatologist, King's College Hospital, and the Royal
Northern Hospital, London

AND

HAROLD T. H. WILSON, M.D., M.R.C.P.

Dermatologist, Central Middlesex Hospital and the Royal
Northern Hospital, London

It is not widely known that nylon hair-nets may cause dermatitis. From the United States, however, Anderson (1950) reported several examples and Barton (1950) added another. In this country two cases were described among six patients also sensitive to dyed nylon stockings (Calnan and Wilson, 1956), and there have been three subsequent reports (Beck, 1957; Calnan, 1957a, 1957b).

Whereas the nylon fibre itself is probably inert, dermatitis may result from sensitivity to resin finish in which the net is coated, to the rubber band which keeps the net in place, and to the dye with which the net is coloured. Most cases are thought to be due to the dye, which is generally of the azo group, a chemical configuration notorious for its capacity to sensitize the skin. None of Anderson's cases of hair-net dermatitis developed dermatitis from nylon stockings, and the two patients described by Calnan and Wilson did not contract the rash from their stockings for over a year after the onset of the hair-net dermatitis.

Clinical Features

The pattern of dermatitis from hair-nets is distinctive enough when complete and uncomplicated. Often, however, the picture is only partially complete and is closely if not indistinguishably imitated by a constitutional seborrhoeic eczema; it may also be complicated by additional areas of dermatitis. Lastly, the patients rarely suspect that their trouble is caused by a hair-net, and it is only in recent

years that we ourselves have become familiar with the condition.

Three principal contact sites are involved—behind the ears, the nape of the neck, and the hairline on the forehead. Retroauricular dermatitis is the commonest, and occurs in almost every instance. It affects the adjacent part of the scalp and may spread down the occipital hair margin to become continuous with patches over the nape of the neck

(see Fig.). The upper half of the ears may show a vesicular dermatitis on both the outer and the inner aspects. Such involvement should make one particularly suspicious of a hair-net contact. Suboccipital and nuchal dermatitis is frequent in women as a manifestation of a seborrhoeic eczema or a neurodermatitis. When due to hair-net sensitivity it is virtually identical with the constitutional condition. Nuchal dermatitis was present in almost every case. A linear dermatitis of the upper forehead and hairline zone was seen in only six patients. It may be so slight as to be missed or disregarded, but when seen has great diagnostic value in the presence of dermatitis of the nape and retroauricular areas. One patient had a striking linear zone of dermatitis under the chin and on the sides of the neck from a hair-net which was tied under the chin with tapes.

The typical pattern may be complicated by areas of eczema or dermatitis elsewhere on the body. In 11 instances dyes of similar nature appeared to be responsible, while in five cases the dermatitis was caused by sensitivity to unrelated substances (Table I). Nine patients had additional areas of dermatitis (Table II) for which we could not find a precise cause.

TABLE I.—Other Sensitivities

16	Stocking		
18			Rubber glove and shoe; mercaptobenzthiazole
19	Hair dye; stocking; paratoluenediamine; yellow nylon blouse	Pink nylon nightdress	Nickel and rubber; mercaptobenzthiazole
21			
24	Stocking		Nickel

TABLE II.—Areas of Associated Dermatitis

Case No.	Skin Involved
4	Whole scalp and nasolabial areas
8	Face
13	Front of chest
14	Elbow flexures
16	Arms
17	Wrists; eyelids
21	Elbow flexures
23	Groins; perineum; axillae
26	Front of chest and elbow flexures

The severity of the dermatitis is usually subacute, consisting of erythema and scaling. It may be moist and exudative behind the ears, and occasionally on the back of the neck. Small vesicles may be found on the tips of the ears and along the hair margin. In one case there was an extremely severe local reaction associated with a widespread petechial eruption closely resembling the rash due to carbromal sensitivity.

Hair-net dermatitis may be persistent or intermittent, according to the frequency with which the net is worn. Some patients wear it for only a few hours after a visit to the hairdresser, while others wear their net regularly.

The age of onset in our cases (Table III) appears to be late when compared with other instances of allergic contact sensitivity, such as nickel (Calnan, 1956) and lipstick (Calnan and Sarkany, 1958). This finding may well have no great

TABLE III.—Age of Onset in 27 Cases of Hair-net Dermatitis

Age	No. of Cases	Age	No. of Cases	Age	No. of Cases
20-9	1	40-9	5	60-9	8
30-9	3	50-9	8	70-9	2

significance from the point of view of allergy, as hair-nets are more often worn by older women, and relatively seldom by younger women with short hair styles.

The duration of the sensitivity when first seen varied from three weeks to seven years. Most patients gave a history of some months. One must admit, however, that a number of cases were not diagnosed for long periods after their first attendance at hospital.

There was no evidence of an atopic diathesis; none had had atopic eczema, and only one patient had hay-fever.

Patch Tests

All the patients except one were patch-test positive to the nylon portion of the hair-net. The one exception (Case 24) was allergic to the rubber of the elastic band but not to the nylon. When patch testing with the rubber, one must take great care to remove all trace of the nylon thread, which is usually wound round the elastic.

In our cases, hair-net sensitivity from the nylon part was always attributable to the dye, and patch tests usually gave an acute vesicular reaction at 48 hours. A single case gave a negative reaction at 48 hours, but was positive when read 48 hours later.

No routine cross-sensitivity tests with the "para" group were done, but patients were tested with any substances which were suspected of causing their other patches of dermatitis. The results are shown in Table I. It can be seen that 11 patients (40%) showed cross-sensitivity dermatitis—a striking illustration of the importance of this phenomenon. Not all patients reacted to chemically related substances, and five cases showed additional unrelated sensitivities.

It is extremely difficult, if not impossible, to trace the precise dye used in a particular patient's hair-net. We have reason to suppose that they are usually azo-dyes, of which there are a large variety. We have patch-tested a number of our patients with paraphenylenediamine, and a red, yellow, and blue azo-dye, and the results are shown in Table IV.

TABLE IV.—Patch Tests to Dyes

Case No.	Paraphenylenediamine	Azo Dyes		
		Red	Blue	Yellow
1	++	+	+	++
2	++	+	+	++
4	+	+	+	++
6	+	+	+	++
7	+	+	+	++
8	+	+	+	++
9	+	+	+	++
10	+	+	+	++
11	+	+	+	++
12	+	+	+	++
13	+	+	+	++
14	+	+	+	++
15	+	+	+	++
16	+	+	+	++
17	+	+	+	++
18	+	+	+	++
19	+	+	+	++
20	+	+	+	++
21	++	+	+	++
22	+	+	+	++
23	+	+	+	++
25	+	+	+	++
26	+	+	+	++
27	±	+	+	++

These particular chemicals are employed in dyeing nylon stockings, but we have no proof that these were the actual dyes used on the hair-nets worn by any of our patients.

Discussion

The fact that we have been able to collect 27 cases within 18 months suggests that this is not a rare condition, and we think it likely that many cases go undiagnosed. The rash produced by sensitivity to nylon hair-nets so closely resembles one of constitutional origin that several of our cases were incorrectly diagnosed when first seen. In spite of increased experience we cannot always distinguish the two conditions by clinical examination alone, and it is essential

that every patient presenting an eczematous rash of this pattern should be asked if she wears a nylon hair-net. If she does so, she should be patch-tested against it. The fact that a patient can wear nylon stockings with impunity does not necessarily invalidate the diagnosis, as many of our patients were able to wear nylon stockings without getting a rash. Even those who did develop a stocking dermatitis did not do so until several months after the onset of their hair-net dermatitis.

One of our cases was sensitive to the rubber band, while the remainder gave positive patch tests to the material of their hair-nets. When tested against a routine batch of azo-dyes used for dyeing stockings, they gave positive reactions, usually to the yellow or red, but occasionally to the blue dye. Although we were unable to obtain the actual dyes used on the nets, we consider that hair-net dermatitis results from sensitivity to the dye in the majority of cases. When the nylon net was discarded, even if replaced by a silk or hair one, the rash cleared. The skin returned to normal after an interval varying from a few weeks to several months.

Summary

Twenty-seven cases of nylon hair-net dermatitis are reported.

Although closely resembling that of seborrhoeic eczema, the uncomplicated rash has a characteristic pattern.

With one exception, sensitivity to the dye appeared to be responsible.

We thank all members of the staff of St. John's Hospital for Diseases of the Skin who referred cases to us; also Dr. Sydney Thomson and Dr. David Williams for allowing us to investigate their cases.

SUCCESSFUL TWIN PREGNANCY
AFTER TREATMENT OF MALIGNANT
ESSENTIAL HYPERTENSION

BY

JOHN H. ROSS, M.B., M.R.C.P., D.Obst.R.C.O.G.
Senior Registrar, London Hospital

AND

JOHN A. WRIGHT, M.B., B.S.

Senior Resident Accoucheur, London Hospital

The benefits resulting from the introduction of lumbo-dorsal sympathectomy and hypotensive drugs in the treatment of malignant essential hypertension are well recognized (Northfield, 1948; Smithwick, 1951; Rosenheim, 1954; Smirk, 1954; Smirk, Doyle, and McQueen, 1954; Pickering, 1955). It is, however, often impossible or impracticable to maintain the blood pressure at normal levels in some patients following one or other of these methods of treatment, although hypertensive symptoms may be relieved, papilloedema may resolve, and progressive renal damage may be arrested. Such patients then resemble those with benign essential hypertension; they may remain free from symptoms, but are still apt to develop cerebrovascular or cardiac complications. In addition, women of childbearing age may suffer the risks of hypertensive pregnancy.

The following report describes a case of malignant essential hypertension first treated by sympathectomy. Hypertension, persisting after sympathectomy, was then controlled with hypotensive drugs and the blood pressure was maintained within normal limits during the greater part of a successful twin pregnancy.

Case Report

A married woman aged 27 was admitted to the Dorset County Hospital in January, 1954, complaining of blurring of vision and retro-orbital pain in the left eye for a few days. She gave no past or family history of renal disease. She was found to have gross bilateral papilloedema with exudates and flame-shaped haemorrhages, more marked in the left retina. Her blood pressure was 260/200 mm. Hg. A diagnosis of malignant hypertension was made, and after treatment with rest in bed and hexamethonium bromide all her symptoms resolved, her blood pressure fell to 200/130, and she was discharged in March.

In April she was admitted to the London Hospital. At that time she was still taking oral hexamethonium bromide. Her blood pressure was 280/150 and there was bilateral papilloedema with retinal exudates, but no haemorrhages. A few discrete enlarged lymph nodes in both posterior cervical triangles and a palpable tip of spleen were also noted.

Investigations on admission gave the following results. Hb, 85% (12.6 g. per 100 ml.); E.S.R., 6 mm. in one hour; blood urea, 39 mg. per 100 ml. Maximum urine urea concentration, 2.88 g. per 100 ml. Catheter specimen of urine: cloud of protein but no casts or excess red cells. Intravenous pyelography and perirenal insufflation of oxygen showed normal excretion of dye and normal renal and adrenal outlines. Excretion of noradrenaline in a 24-hour specimen of urine was normal. Chest x-ray examination showed normal-sized heart and no pulmonary lesion. The diagnosis was essential hypertension in the malignant phase.

During the next few weeks further enlargement of the cervical glands and spleen was noted, but she remained asymptomatic and afebrile. Repeated blood counts and chest x-ray films were normal and her blood Wassermann reaction was negative. A cervical gland biopsy showed reticulum-celled hyperplasia with a slight increase of plasma cells and focal fibrosis. This was thought to be probably due to chronic inflammation, but a reticulosis could not be excluded. The glands have since decreased in size and the spleen has only occasionally been felt. With rest in bed and oral hexamethonium bromide her blood pressure varied between 160/110 and 230/160 in the supine position. The response to treatment was not considered satisfactory, and in July and August, 1954, bilateral thoracolumbar sympathectomy (T 5 to L 3) and splanchicectomy was performed. Before operation her blood pressure varied between 210/150 and 270/220. After operation there was only a slight fall in her blood pressure, and three months later it was 195/110 in the supine position. A biopsy of the right kidney at the time of operation showed medial hypertrophy of all arterioles with marked subintimal hyalinization but no fibrinoid necrosis. Of 28 glomeruli, six were completely hyalinized, six had shrunken tufts with marked capsular fibrosis, and the remainder showed focal necroses and capsular adhesions. There was focal collagenous increase in the interstitial tissue with patchy tubular atrophy. These changes were thought to be the result of hypertension rather than of primary renal disease.

During the next two years she received no hypotensive therapy and remained well apart from slight shortness of breath on exertion and an occasional frontal headache when fatigued. She worked as a full-time schoolteacher. She wanted children, but was advised against pregnancy. On her annual visits to the London Hospital out-patient department her blood pressure was about 210/130 with a slight postural fall. A cloud of protein persisted in her urine. The optic disk edges remained blurred and the physiological

cups could not be seen, but the papilloedema had resolved. The retinal arteries remained tortuous, and many new vessels appeared around the disk margins. Haemorrhages and exudates were no longer to be seen (see Fig.).

In November, 1956, at her annual visit to the out-patient department, she thought she was two months pregnant (L.M.P. September 18; E.D.D. June 25, 1957). A 24-hour rat pregnancy test was positive, and she was admitted for consideration of termination of pregnancy. On examination her blood pressure was 220/135 in the supine position. The fundi were unchanged and her visual acuity was (R) 6/5 and (L) 6/6. Her urine still contained a cloud of protein.

Investigations in December, 1956, showed: Hb, 92% (13.6 g. per 100 ml.); blood urea, 36 mg. per 100 ml.; maximum urine urea concentration, 1.5 g. per 100 ml.; E.C.G. left axis deviation. Chest x-ray examination showed no cardiac enlargement.

Right optic fundus, March 19, 1957. Optic disk flat, but edges blurred and physiological cup not visible. Many new tortuous vessels around the disk margins.

It was considered that the chances of a live birth were small and that there was a risk of further hypertensive damage if the pregnancy was allowed to continue; termination was therefore recommended. However, the patient and her husband were both keen to allow pregnancy to continue with a trial of hypotensive therapy. It was finally decided that termination in a symptomless and reluctant patient might have an adverse psychological effect, and, as the results of strict hypotensive therapy in pregnancy were not yet clearly established, she was allowed to continue under careful supervision.

She began treatment (12 weeks pregnant) with reserpine, 0.25 mg. three times a day, mecamlamine, 1.25 mg. four times a day, and phenobarbitone, $\frac{1}{2}$ gr. (32 mg.) twice a day. No salt was added to her food and she was at rest most of the day. Within a few days her urine became free of protein and it remained so throughout her pregnancy. Her blood pressure fell, and during the next month it remained at about 139/95 when supine and 130/80 when standing. The highest levels recorded were 190/120 when supine and 160/110 when standing. In January, 1957, she was discharged from hospital on the same treatment. At 18 weeks her uterus was noted to be unduly large, and radiography confirmed twin pregnancy. During the following weeks her weight rose excessively and her blood pressure slightly. In February (22 weeks) her blood pressure was 160/100 when supine and 140/100 on standing. The dose of mecamlamine was increased to 2.5 mg. three times a day. However, there was no significant fall in her blood pressure, and in March (26 weeks) she was readmitted for observation. During the next 10 weeks she was allowed out of bed for toilet purposes only. She remained well apart from minimal dyspnoea and very occasional hypotensive symptoms on standing. Her blood pressure fluctuated considerably, but was usually about 135/90 when supine and 120/80 when standing. The highest levels recorded were 200/140 when supine and 170/110 when standing. Her weight gain was

not excessive, and an increase of 32 lb. (14.5 kg.) from the eleventh to the thirty-sixth week was regarded as normal for a twin pregnancy. There was no oedema and her blood urea remained normal. Lower-segment caesarean section at about 36 weeks was contemplated, and at 34 weeks an x-ray examination of the abdomen was made to estimate the foetal size and maturity. This showed both foetuses to be presenting by the vertex, with the placenta situated in the upper posterior part of the uterine wall. The absence of any lower femoral epiphyses suggested that the foetuses were not more than 36 weeks at the maximum.

At the 36th week of pregnancy (May, 1957) the membranes ruptured spontaneously. Following a first stage of four hours' duration, during which the patient had no pain, two live female infants were delivered by forceps under general anaesthesia (nitrous oxide, oxygen, trichlorethylene, and ether). A normal third stage followed, with the delivery of a healthy binovular placenta. The first twin, weighing 3 lb. 2 oz. (1,430 g.), cried spontaneously at birth and was of good tone and colour. The second twin, weighing 4 lb. 6 oz. (1,985 g.), showed marked blue asphyxia at birth, with little response to pharyngeal suction, intragastric oxygen, and intravenous nalorphine hydrobromide. Normal respiration was finally established some 20 minutes after delivery following intubation and aspiration under direct vision, combined with artificial respiration. During the puerperium, trials were first made with mecamlamine, 2.5 mg. three times a day, and reserpine 0.25 mg. twice a day, separately. Neither produced a sustained fall in blood pressure, and in the fifth week mecamlamine, 2.5 mg. twice a day, was combined with reserpine, 0.25 mg. twice a day, and her blood pressure dropped to a steady level of about 150/100 when supine. In the third week of the puerperium her blood urea was 30 mg. per 100 ml., maximum urine urea concentration 1.27 g. per 100 ml., and creatinine clearance 81 ml. per minute. She remained asymptomatic, gradually increasing her activities until she was up through-out the day breast-feeding and caring fully for her twins. Both infants thrived; after a short period of tube feeding they were later breast-fed on demand. On discharge from hospital, aged 6 weeks, the first twin weighed 4 lb. 11 oz. (2,125 g.) and the second 5 lb. 11 oz. (2,580 g.).

Discussion

Pregnancy in patients with essential hypertension in the malignant phase is rare, and before satisfactory treatment was introduced termination was always recommended (Fishberg, 1954). There is no record of a successful pregnancy in an untreated patient. There have been several reports of pregnancies following sympathectomy. Newell and Smithwick (1947) reported 14 cases, three of which had had malignant hypertension. Two of these were described as having pyelonephritis also. The blood pressure was only slightly raised at the onset of their pregnancies, which occurred nine months, one year, and four and a half years after sympathectomy. One of these pregnancies was uneventful; one patient had no rise in blood pressure during pregnancy, which was terminated by caesarean section; and one had a surgical induction at the 38th week following increasing hypertension and proteinuria.

Peet (1948) reported 34 pregnancies in 28 women following sympathectomy. None are described as having had malignant hypertension. Eighteen had maintained normal blood pressure levels after operation and before pregnancy, slightly raised at the onset of their pregnancies, which occurred nine months, one year, and four and a half years after sympathectomy. One of these pregnancies was uneventful; one patient had no rise in blood pressure during pregnancy, which was terminated by caesarean section; and one had a surgical induction at the 38th week following increasing hypertension and proteinuria.

d'Abreu (1953) described four cases of successful pregnancy after sympathectomy. Again none had hypertension in the malignant phase prior to operation.

The use in pregnancy of hypotensive drugs, including mecamlamine and pentolinium tartrate with or without rauwolfia alkaloids, has not yet been adequately reviewed. Hexamethonium and pentolinium tartrate are perhaps more

effective in the treatment of pre-existing hypertension in pregnancy than of "toxaemic" hypertension (Morris, 1953; Blair, 1954; Townsend, 1955). Hydrallazine hydrochloride should theoretically have special value as a hypotensive agent, since it increases renal blood flow, but it has a toxic effect resembling disseminated lupus erythematosus (Morrow, Schroeder, and Perry, 1953). Veratrum alkaloids have been shown to produce acute reduction of blood pressure and to improve the outlook for the mother more than the child in the presence of "toxaemia" (Morris, 1955).

The risks to mother and foetus in pregnancy when there is pre-existing hypertension are well known; but the long-term effect on blood pressure of pregnancy in such cases is still not clearly defined (Browne, 1947; Chesley and Annitto, 1947; Chesley, Annitto, and Jarvis, 1947). Multiple pregnancies are known to predispose to hypertensive "toxaemia" more frequently than single pregnancies (Brews, 1953). Our patient risked complications in pregnancy due to pre-existing hypertension, and her chances of an added "toxaemia" were increased by the twin foetuses. It cannot, however, be claimed that the treatment during pregnancy prevented additional "toxaemia," the development of which is unpredictable in any individual patient.

The ease of maintenance of normal levels of blood pressure in this patient with small doses of mecamlamine and reserpine was striking. This successful combination of sympathectomy with hypotensive drugs has been observed by one of us (J. H. R.) in other patients. Although sympathectomy for severe hypertension has been employed less in recent years, it still has a place in the treatment of patients with malignant essential hypertension in whom large doses of hypotensive drugs are ineffective or produce severe side-effects but who are fit enough to withstand the operation. If necessary, smaller doses of the drugs may be tried afterwards.

The neonatal asphyxia of the second twin was probably not related to the mother's treatment, and it would appear that the hypotensive drugs had no ill effects on the infants (their blood pressures were not recorded). It has been observed that hexamethonium passes freely into the amniotic fluid, and swallowing of the fluid has been suggested as being responsible for neonatal deaths by Morris (1953), who described the treatment of 26 pregnant women with hypertension. There were 7 stillbirths and 19 live births, with 7 neonatal deaths (within eight days). There is no information available yet about the transference of mecamlamine across the placenta.

Summary

A successful twin pregnancy 33 months after the mother had undergone bilateral thoracolumbar sympathectomy for malignant hypertension is described. Hypertension persisting after the operation was controlled with mecamlamine and reserpine.

We thank Lord Evans and Mr. Alan Brews, under whose care this patient was treated at the London Hospital, and Professor Clifford Wilson for their help in the preparation of this paper.

Summary

Direct anti-globulin tests on the red cells from fresh clotted blood from 100 cases of malignant disease gave negative results. Positive results were obtained if the specimens were stored overnight at 4° C.

Indirect anti-globulin tests on the sera from some of these cases gave positive results against fresh group O rhesus-positive cells at 4° C. only, but this was abolished by previous absorption of the serum with secretor saliva. It was considered that the antibody involved was the incomplete cold auto-antibody described by Dacie (1950). Possible reasons for the discrepancy with other workers are discussed.

My thanks are due to Dr. J. Stewart and Dr. L. A. D. Tovey, of the Bland-Sutton Institute, and to Dr. A. E. Mourant and Dr. D. Parkin, of the Lister Institute, for their help and encouragement. Appreciation is also expressed to Dr. J. S. Campbell, of the Aberdeen Blood Transfusion Service, for supplying the goat anti-globulin serum.

Medical Memorandum

Caeco-colic Intussusception Following Appendicectomy

In 1953 Cleland found records of only five cases of intussusception in the immediate post-operative period following appendicectomy, and to these he added a personal case. A further case is here recorded.

CASE REPORT

A boy aged 10 was admitted to hospital on December 8, 1956, with a history of abdominal pain for 18 hours and the signs of acute appendicitis. Appendicectomy was performed the same evening through a muscle-splitting incision, and an acutely inflamed appendix, wrapped in omentum, was found, together with some free turbid fluid. The appendicectomy was carried out with the customary ligation of appendix stump and purse-string invagination, without carbolizing the base, and the abdomen was closed without drainage.

Recovery was at first uneventful, and an enema was given on the fourth post-operative day with a good result, but on the fifth evening he was seen because of a sudden attack of severe colicky pain, which made him cry out and draw up his legs in each spasm. On examination the general condition was good, pulse and temperature were normal, and the abdomen was soft between spasms, with no distension. Palpation over the ascending colon seemed to induce painful spasms and guarding, but no mass could be felt. Bowel sounds were slightly increased. Rectal examination was negative. Two hours later he vomited, but was easier, and soon went to sleep.

At 7 a.m. the next day he had a recurrence of the severe pain, and he vomited again, though his general condition was unchanged and pulse and temperature were still normal. However, inspection of the abdomen showed fullness on the right side, while palpation suggested a vague mass in the upper right abdomen, and induced severe pain and spasm. Bowel sounds were increased. The lower rectum contained constipated faeces, and inspection of the finger-stall revealed a small fleck of blood-stained mucus, more evident when wiped on to a piece of lint. A clinical diagnosis of intussusception was made. A portable scout x-ray examination

of the abdomen was made, but it added no further information. A white-cell count was 13,500 per c.mm.

At operation 14 hours after the onset of symptoms, through a right paramedian incision, a few ounces of clear yellow free fluid was found and the diagnosis of intussusception confirmed, the apex having reached the middle of the transverse colon. Reduction was at first easy, but towards the end the ensheathing layer serosa split, and required oversewing. The whole was quite viable and little altered in colour, except for the apex. The small bowel was noted to be only slightly distended. The apex was the previously inverted base of the appendix, and in the final reduction a little pus exuded from the centre of the purse-string, while the caecum for 2 cm. round was firm with oedema and reddened. The pus was let out and mopped away, and a little penicillin-sulphathiazole powder applied. No attempt was made to fix the caecum to the parietes, and the abdomen was closed without drainage.

Post-operatively, intravenous N/5 glucose saline was given, 1 pint (570 ml.) six-hourly for 48 hours, and fluids only by mouth were continued to four days, when solids were started. Tetracycline, 250 mg. six-hourly, was given with the intravenous fluid, then changed to 125 mg. six-hourly by mouth for three further days, in view of the abscess found at the appendix stump. On the third day the child developed a right lower lobe collapse, which readily cleared with intensive physiotherapy. Three weeks after the second operation he returned home. He has since been seen twice at the out-patient department and has been well, with a good appetite, regular bowel action, and no chest complaint; both wounds were soundly healed.

COMMENT

In the seven recorded cases, including the present one, the age of the patient has been between 4 and 28 years. With one exception (on the twelfth day), the onset has been remarkably constant at about the fifth post-operative day.

The difficulty in diagnosis has been stressed by previous writers. Slight post-operative colic is not unusual some days after abdominal operations, but the severity of the intussusception colic was striking. Abdominal palpation is rendered difficult by the recent tender wound, though a mass was felt in four of the seven cases. Cleland stated that the absence of haemorrhage from the bowel seemed absolutely constant, but this is refuted by the present case.

In four recorded cases and in the above one a small abscess was present in the space enclosed by invagination of the appendix stump. Such abscesses have been noted at post-mortem examination soon after appendicectomy for acute disease, and it seems likely that they occur in many more instances never recognized. Cases have also been recorded where such an abscess ruptured into the abdomen, with the appearance of a ruptured viscus.

The rarity of intussusception is interesting in view of the "tumour" which must frequently be created by the oedema surrounding the invaginated and infected appendix stump on so many occasions. The infective element seems important, as no case has been recorded following a "cold" appendicectomy.

These possibilities give support to the view that, except where the stump is friable and insecure, careful ligation alone may be wiser than the added purse-string.

I thank Mr. H. E. Lockhart-Mummery for permission to publish this case and for his advice and encouragement.

Reviews

CELL BEHAVIOUR

The Life and Death of Cells. By Joseph G. Hoffman. (Pp. 288. 35s.) London: Hutchinson Scientific and Technical Publications. 1958.

To produce a scientific book that holds the attention of the general reader from cover to cover is something achieved by few research workers. But to write with engaging enthusiasm, yet with all the wiles and devices of modern biophysics, about the complicated behaviour of normal and malignant cells must be a unique achievement. Here are some of Joseph G. Hoffman's chapters: "What is Life?"; "Automation in Cells"; "Variations and Mistakes"—an exciting survey of chromosome counts and chromosome breakage; "Cancer Cells"—which begins with the provocative sentence, "Cancer is a disease of organization, a cell mistake in tissues where the number and growth of cells is precisely regulated"; "Submicroscopic Fibres"—concerned with collagen and fibres of tissue cells, bacteria, and algae; "Games of Chance"—we are initiated into statistical mechanics before considering cell multiplication by the so-called Monte Carlo method; and "The Importance of Death." I especially enjoyed the exciting account of physical forces that govern the organization of molecules both outside and within cells. The discussion of van der Waals's forces is masterly. Biology seems to be aiding pure chemistry almost as much as chemistry is helping biology in this field. No doubt many of the author's views will not be acceptable to all cancer research workers, but at least they will arouse vigorous discussion, which is something to be thankful for nowadays. I strongly recommend this delightful book to readers who enjoy the unusual. A few references to assist further reading and some well-planned diagrams would have been acceptable. The index is adequate, but the price is far too high. ROY CAMERON.

HAEMORRHAGIC DISEASES

Haemorrhagic Diseases. By Armand J. Quick, Ph.D., M.D. (Pp. 451; illustrated. 70s.) London: Henry Kimpton. 1957.

Any book written by so distinguished a haematologist as Professor Quick must attract attention. Haemorrhagic disease is a subject which has long interested him, and his disease is a subject which has long interested him, and his many previous publications are summarized and expanded in this book. Divided into seven chapters, it includes a historical review, the theories of blood coagulation and its role in haemostasis, and the hypoprothrombic states dependent both upon pathological conditions and on drugs. Haemophilia, pseudohaemophilia, purpura, and telangiectasia are also fully discussed, and there are chapters on afibrinogenemia and hyperheparinaemic states. Venous thrombosis is nicely summarized in a short section. Finally a selection of laboratory techniques is given, especially emphasizing those devised by Quick and his colleagues.

This book is bound to cause controversy, as not all Quick's hypotheses are acceptable to other experimental haematologists. To parody Abraham Lincoln, "You can satisfy some of the people all the time, and all the people some of the time, but you cannot satisfy all the people all the time," and this gives a very real picture of the present state of blood-clotting research. Thus, though individual readers of blood-clotting research. Thus, though individual readers may disagree with parts of this book, yet it is an excellent exposition of Quick's beliefs and a serious contribution to haematology. During a life devoted to blood diseases he has seen many rare conditions, and his clinical observations are excellent. The general get-up and printing of the book are uniformly good, but there are too many spelling and small factual errors which give the appearance of carelessness in compilation and proof-reading. The very considerable bibliography is arranged at the ends of the individual

chapters, and there is no general author index. This is a book for the qualified haematologist rather than for the student. H. PAYLING WRIGHT.

RELATIONSHIP BETWEEN LIVER AND BRAIN

Liver-Brain Relationships. By Ian A. Brown, M.D., Ph.D. (Pp. 198+xiii; illustrated. 50s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1957.

It is certainly convenient to have the complicated and expanding problems of liver-brain relationships discussed in an impartial and clear fashion within the compass of a tidy monograph. The clinical, morbid anatomical, and biochemical aspects of the subject-matter are of considerable interest to physicians. What was not so very long ago yet another clinico-pathological rarity—mysterious, incurable—has now on analysis proved to hold more important biochemical mechanisms. Still more wonderful, this unpromising morbid process would seem to turn out to be reversible—to some extent, at any rate. Neurologists who approach the problem of the liver-brain axis from the angle of Wilson's disease, and internists who deal with the hepatic comas, will unite in finding this volume of some interest and assistance. Unfortunately, in a presumed scientific approach where scrupulous accuracy in nomenclature is to be expected, there are many misspellings—for example, Bromwell, Walsh, Luthy, Lowy, Gyorgy. But most disturbing of all is a recurring reference to a certain Cambridge professor of anatomy whom the author terms Glissonii. Confidence in the exactitude of the rest of the volume is somewhat shaken. MACDONALD CRITCHLEY.

PRACTICAL MIDWIFERY AND GYNAECOLOGY

A Practical Handbook of Midwifery and Gynaecology for Students and Practitioners. By W. F. T. Haultain, O.B.E., M.C., B.A., M.B., B.Ch., F.R.C.P.Ed., F.R.C.S.Ed., F.R.C.O.G., Clifford Kennedy, M.B., Ch.B., F.R.C.S.Ed., F.R.C.O.G., and J. L. Henderson, M.D., F.R.C.P.Ed. Fifth edition. (Pp. 410+x; illustrated. 30s.) Edinburgh and London: E. and S. Livingstone. 1957.

It is five years since the latest edition of this popular book was published. The authors, well-known figures in the obstetric world of Edinburgh, have thoroughly revised the present edition. The section on "The Infant and Infant Feeding" has been rewritten, and there are new chapters on the difficult subject of the Rh factor and also on psychology in obstetrics—a chapter that is particularly apposite in view of the increasing emphasis that is being placed on the emotional aspects of pregnancy. The style is synoptic, and thus the busy practitioner will find reference easy and rapid. But it is difficult to reconcile, in a book of this character and compass, the inclusion of descriptions (and illustrations) of gynaecological operations which a general practitioner will not be called upon to perform. However, this is a criticism that can be applied to many textbooks written for medical students and general practitioners. The views expressed are conventional, and their presentation will appeal especially to final-year students. For those who wish for a simple and lucid vade-mecum in obstetrics and gynaecology this book can be safely and unhesitatingly recommended. W. C. W. NIXON.

HOST-PARASITE RELATIONSHIPS

Host-Parasite Relationships in Living Cells. A Symposium sponsored by the James W. McLaughlin Fellowship Program, University of Texas—Medical Branch, Galveston, Texas, April 27, 1956. Compiled and edited by Harriet M. Felton, M.D. (Pp. 245+xix; illustrated. 50s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1957.

This volume is a report of the proceedings at a symposium held in Galveston, Texas, on April 27, 1956. There were eleven participants, eight of whom contributed papers. One session was devoted largely to the morphology of the host cell and of bacteria as revealed by the electron microscope,

and of cells in tissue cultures inoculated with viruses; these three contributions by E. W. Dempsey, C. E. Georgi, and J. T. Syverton are beautifully illustrated. A long paper by R. A. Good is entitled "The Morphological Basis of the Immune Response" and includes a valuable review of the development of knowledge about the site of formation of antibodies; the incrimination of the plasma cell is supported by copious evidence from the clinical field relating the gamma-globulin content of the blood with the numbers of these cells in the body. A thoughtful paper by R. J. Dubos deals with the interrelationships of host and micro-organism, and one by M. G. Sevag on similar lines concentrates on the properties of the micro-organism which confer pathogenicity. The authors of these and other papers finally engaged in a round-table discussion at the end of what must have been a most exhausting although stimulating day. This and other discussions are reported apparently verbatim, including trivial remarks and reference to other contributors by such names as "Charlie" and "Jerry." The subject of this symposium is so fundamental and in many ways obscure that the speakers inevitably posed more questions than they answered, but their contributions make up an interesting, and at many points illuminating, review of it. The papers conclude with sometimes extensive lists of references.

L. P. GARROD.

TREATMENT OF BLADDER TUMOURS

Bladder Tumours: A Symposium. By Mitchell Brice II, M.D., and eleven others. (Pp. 92+vii; illustrated. 32s.) Philadelphia and Montreal: J. B. Lippincott Company. London: Pitman Medical Publishing Co., Ltd. 1957.

Tumours of the bladder give rise to one of the most depressing problems in surgery. In spite of the introduction of a number of new methods of treatment the prognosis still remains poor. Any advance in the treatment of these tumours is likely to be small and slow. The importance of having a basic standard from which to judge such advances is obvious, and the authors of this symposium from three well-known New York institutions have combined to give such a baseline. One of the main difficulties in assessing the value of various types of treatment of bladder tumours is the wide variations in pathological classification which have been adopted in different clinics. In this book these tumours have been classified by a combination of histological grading following Broders's plan and a classification depending on the stage of penetration of the bladder wall and metastatic spread. Throughout it is shown how closely related are these two classifications and that the prognosis runs parallel to both. A valuable series of untreated bladder tumours has been collected, and this series forms a very salutary standard with which to compare other forms of treatment. The treatment of bladder carcinoma by perurethral local excision and fulguration is shown to have been mainly confined to localized and low-grade cancer, and in such it apparently prolongs survival, removes a great deal of bladder irritability, and stops haematuria; but if hydronephrosis is present the tumour is probably of a higher grade than was expected, with a corresponding impaired prognosis. The results of partial cystectomy are shown to be reasonably satisfactory for low-grade and non-penetrating carcinomata, but leave much to be desired in the treatment of high-grade and late-stage cancers. Similarly it is shown that total cystectomy which removes only the bladder but leaves much pelvic connective tissue and lymphatics yields results in the case of high-grade carcinomata which must be improved. This indicates the trend towards more radical surgery for the higher-grade and more widespread cancers. A detailed description of a radical total cystectomy in which all the pelvic cellular tissue is excised with or without the rectum is given, and the results of the first 100 cases are recorded. This operation is considered to be a definite improvement upon simple total cystectomy. Finally the surgical treatment of cancer of the bladder is discussed and summarized.

This symposium is a very valuable contribution to the treatment of cancer of the bladder by collecting large series

and evaluating statistically the various methods of treatment. For not only will it be found invaluable for those surgeons who require statistics for comparison with those of new methods of treatment, but it will be found most stimulating reading for any surgeon who has to treat this most resistant disease.

J. E. SEMPLE.

THE RORSCHACH TEST

Perceptualists. A Fundamentally Reworked, Expanded, and Systematized Rorschach Method. By Zygmunt A. Piotrowski, Ph.D. (Pp. 505+xvii; illustrated. 47s.) New York and London: Macmillan Company. 1957.

Hermann Rorschach was a Swiss psychiatrist of undoubted brilliance who died in 1922 at the early age of 38. From Freud he acquired understanding of psycho-analysis; from Jung an interest in psychodiagnostic procedures and in typological studies of personality. Rorschach's main contribution—as is well known—is the ink-blot test that has come to bear his name. This method he evolved gradually as an empirical research tool, and was careful to specify that its theoretical foundation was in no sense complete. Although its validity has been questioned in some quarters, the method has proved of real, if limited, usefulness in psychiatric diagnosis and in the appraisal of certain aspects of personality. Dr. Piotrowski now endeavours to claim for the Rorschach method the status of a science in its own right, to which he gives the clumsy title of "perceptanalysis." It is difficult to see what is gained by such a claim, which would quite certainly have been disowned by Rorschach himself. Although scientific principles may be applied in the design of any psychological test, the results do not for that reason constitute an addition to scientific knowledge. In many cases, indeed, their apparent objectivity is deceptive. In the case of the Rorschach test, even the results are doubtfully objective, and there is certainly no theory of personality sufficiently well established to endow them with scientific validity. Why not simply treat the method, as did Rorschach, as an empirical technique of heuristic value in psychological medicine?

It is only fair to add that Dr. Piotrowski has made a sincere and careful study of the Rorschach method, based upon his own extensive experience and the findings of other workers. This will be of interest and value to clinical psychologists and others concerned with the minutiae of Rorschach interpretation. It is doubtful, however, whether his treatment of scoring problems will displace that of Klopfer and Kelly, which is widely followed in this country. None the less, Dr. Piotrowski's book is a solid and thoughtful contribution to the technical literature and can be recommended to all who feel the fascination of Rorschach's original experiment.

O. L. ZANGWILL.

The fascination of retreading the paths of history or romance can be compelling. Some may be content to walk the Pilgrims' Way from Winchester to Canterbury, but others, answering a more adventurous call, must break right away and follow in the footsteps of Livingstone through the jungles of Africa or of Marco Polo over the desolate expanses of Asia. Sir John Elliot, chairman of the London Transport Executive, has reserved for himself a small corner of this particular historical field, and very rewarding it has turned out to be. In *The Way of the Tumbrils* (Max Reinhardt, London; price 18s. net) he records his detailed and scrupulous researches in those areas of Paris where the main events of the French Revolution took place and where it is still possible to find traces of the men and women who played the leading parts in that extraordinary drama. With an informed and sympathetic pen he writes of those who lived, worked, declaimed, plotted, were imprisoned, died, and were buried in revolutionary Paris—among them the king and queen, Charlotte Corday, Marat, Danton, and Robespierre. Furnished with a useful plan and a brief outline of the Revolution, this book is the satisfying outcome of one professional man's hobby. There are no dry bones of history about it, for every page reflects the author's manifest enthusiasm for his subject. Anyone with a few days to spend in Paris would find it a pleasantly unconventional addition to the standard guide-books.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 30 1958

ASPIRATION OF FOOD AND VOMIT

In view of the way the respiratory and alimentary tracts cross each other in the pharynx, it is a constant source of wonder that aspiration of food is not an everyday occurrence. The anatomical conformation of the pharynx and larynx and the beautiful, though complicated, mechanism of swallowing effectively seal the larynx, preventing aspiration in ordinary circumstances. Should this mechanism fail for an instant, the extraordinarily sensitive protective reflexes guarding the larynx and air passages see to it that any foreign material, even a crumb, that gets into the trachea is quickly coughed out by the most vigorous efforts of which the subject is capable. Now evidence is accumulating that in circumstances other than "normal"—and these abound in medical practice—

aspiration is much more common than is realized. That aspiration can be responsible for death in patients made unconscious by drugs or disease, when the normal protective reflexes are depressed, has long been known. A. M. N. Gardner¹ directs our attention to other cases of hitherto inexplicable deaths and complications which may well have been due to aspiration. Perhaps the two most noteworthy fields of medicine in which these cases occur, though there are many others and hardly any is exempt, are paediatrics and anaesthesia. For infants, the aspiration of a large quantity of milk (the "milk embolism" of Marie²) may be immediately fatal, particularly if they are feeble. Even repeated small aspirations—not at all infrequent in ill or feeble infants—may give rise to a variety of complications depending on the nature of the material aspirated. In anaesthetized patients aspiration of the contents of the stomach is still a major cause of death.³ A full stomach, so common in patients with intestinal obstruction and in women in labour, with pharyngeal and oesophageal sphincters paralysed by relaxants, and reflexes depressed with barbiturates, form a combination particularly conducive to regurgitation and aspiration.

¹ Gardner, A. M. N., *Quart. J. Med.*, 1958, 27, 227.
² Marie, J., Sorlingo, P., and Hébert, S., *Sem. Hôp. Paris*, 1947, 23, 1335.
³ Edwards, G., Morton, H. J. V., Pask, E. A., and Wylie, W. D., *Anaesthesia*, 1956, 11, 194.

The evidence that aspiration had occurred before death, even though perhaps agonal, rather than after death, is usually taken to be the presence of gastric contents in the bronchi and lungs at necropsy. To test this belief, Gardner placed barium sulphate in the stomach immediately after death. Radiographs taken at necropsy 24–48 hours later showed barium in the lungs in 7 out of 10 bodies. The validity of such a fundamental means of proof as necropsy has therefore been shaken, and for this evidence to be acceptable in future measures must have been taken immediately after death to prevent post-mortem gravitation of gastric contents into the lungs. Gardner went on to investigate the frequency with which aspiration takes place in life. Barium was placed in the drinks of patients after abdominal operations. In 10% barium reached the lungs. That this was due to aspiration of food and not vomit was shown by the rarity of the occurrence when the drinks were placed in the stomach by tube. The diagnosis that aspiration has occurred in these circumstances is just as difficult during life as it is after death. Staining of the sputum, coughing after drinking, pyrexia, tachycardia, and hypotension are all suspicious findings.

Aspiration is clearly a hazard of illness rather than of health and is particularly liable to occur when feeding recumbent patients who are old, ill, and perhaps even narcotized. Prevention lies in insisting on drinking being carried out in a sitting position only. For cases in which this is impossible the common hospital feeding-cup appears to need redesigning, or drinking through a straw might be substituted for it. Gardner points out that the shape of the spout of the standard hospital feeding-cup "enables fluid to be poured into the mouth and down the trachea of a recumbent patient, and the hooded top, by concealing from him both the quantity and orientation of the fluid, ensures that he is taken by surprise."

Aspiration of food or vomit is an important event in any circumstances. In the surgical wards it is probably responsible for some cases of post-operative chest disease, while in the medical wards it may yet emerge as an important aetiological factor in some common pulmonary diseases. Outside hospital, aspiration may kill at all ages, and in a variety of circumstances: the feeble infant in its cot, the heavy feeder intoxicated with alcohol on his couch, and the epileptic in the street, are but a few examples. Any case of otherwise inexplicable death should be suspect, and aspiration as a factor carefully excluded. However, if the diagnosis of aspiration is to be made at necropsy, it is worth bearing Gardner's work in mind. Pathologists will no doubt study his experiments and results with particular interest.

any treatment has real prospect of lasting success once irreversible vascular changes have occurred in the kidneys or other vital organs. Effective hypotensive therapy in malignant hypertension has to be started at the earliest possible moment if life is to be saved.

Total adrenalectomy may have an appeal on the grounds that an operation can produce a cure without dependence on hypotensive drugs which are difficult for the patient and physician to manage, but after the operation patients are wholly dependent on adrenal cortical replacement therapy, and on achieving a critical balance between the hazards of hypertension on the one hand and of adrenal cortical failure on the other. Arnott and his colleagues consider that total adrenalectomy should not be attempted unless medical measures have failed, and never employed in the presence of frank renal failure. But it may offer a reasonable hope of cure of severe hypertension if drug treatment has failed.

DRY LABOUR

For generations "dry labour" has had the connotation of long and tedious travail; but not now. To-day premature rupture of the membranes is not regarded as a disadvantage, provided it does not betoken disproportion or malpresentation. This view is upheld by the findings in an investigation by M. N. Bainbridge and his colleagues from University College Hospital, London, into the effect of rupture of the membranes on length of labour.¹ A total of 3,750 consecutive deliveries, 62% of them in primigravidae, were analysed, omitting only multiple pregnancies and those ended by caesarean section. The cases were divided into four groups according to the time of rupture of membranes. The first group contained all those cases in which labour was induced by amniotomy; the second group comprised those in which the membranes burst spontaneously before or at the very outset of labour; the third group was of those in which the rupture occurred during the first stage of labour; and the final group was confined to those in which the membranes were intact until at least full dilatation of the os. The analysis showed clearly that both in primigravidae and in multigravidae the first stage of labour was shorter in the first two groups—that is, when the membranes ruptured or were ruptured at or before the onset of labour. Moreover, this advantage accrued without there being any adverse effect on the duration of the second stage or on the incidence of forceps delivery, manual removal of the placenta, or post-partum haemorrhage. No evidence was found that rupture of the membranes before labour increased the rate of genital sepsis, but it has to be noted that all patients in this series who were undelivered 24 hours after the rupture were given antibiotic therapy. Nor was foetal distress more common, but the exclusion of all labours terminated by caesarean section, which might in some cases have been indicated by foetal distress, casts some doubt on the validity of this finding.

¹ Bainbridge, M. N., Nixon, W. C. W., and Smyth, C. N., *J. Obstet. Gynaec. Brit. Emp.*, 1958, 65, 189.
² Embrey, M. P., *ibid.*, 1953, 60, 37.
³ Eastman, N. J., in *Williams' Obstetrics*, 1956, 11th ed., p. 423. Appleton-Century-Crofts, New York.

Bainbridge and his colleagues did not investigate the effect of delay in the onset of labour following rupture of the membranes, but M. P. Embrey² has presented an interesting report on this aspect. He found that delay in the onset of labour after spontaneous premature rupture of the membranes increased the length of labour; so that with a 24-hours interval the incidence of prolonged labour was increased by half, and with a 72-hours interval it was doubled. More important was his finding that if labour did not start within 48 hours of rupture of the membranes the foetal mortality was doubled, while a 96-hours latent period trebled the foetal loss. N. J. Eastman³ showed that a distinction must be made according to whether the foetus is mature or premature at the time of spontaneous premature rupture of the membranes. In mature babies he found a perinatal mortality of 1.7% when the latent period before the onset of labour was less than 48 hours, but four times as much (6.8%) when the interval was more than 48 hours. It follows that, if the baby is adjudged mature, steps should be taken to stimulate the onset of labour in the baby's interest. In premature babies, however, Eastman found that the perinatal loss was determined largely by the degree of prematurity. When, therefore, there is premature spontaneous rupture of the membranes and the pregnancy is still some weeks before term, the mother is best admitted to hospital so that if labour does follow quickly the baby can enjoy the readily available facilities of the premature nursery; but uterine action is not stimulated, in the hope that the pregnancy will continue—as it often does—until the foetus is larger and more likely to survive.

RELAXATION

Later generations looking back on the 1950's may well think that one of the more overworked fashions of the decade is relaxation. A leading banker returning from his Riviera holiday is "bronzed and relaxed"—at least if popular with the newspapers. A Cabinet Minister appearing on television gives a "relaxed performance"—or so his supporters will declare. Relaxation is thus a term of praise; your friends have it and your enemies do not. There may be an insignificant minority who would rather see their public men looking eager, alert, enthusiastic, even occasionally in these times worried, but to the great majority of right-thinking people a "relaxed" man is one who has an easy mastery of men and affairs.

In contrast, this mythology delineates an unrelaxed man: he is a business executive who is always on the go, and he suffers from anginal attacks, hypertension, arteriosclerosis, and possibly peptic ulcers. Or, as R. E. Lee and R. F. Schneider,¹ of New York, put it: "In relatively recent press reports, several writers have highlighted a close association between cardiovascular disease and the strains of executive responsibility." To test the truth of this hypothesis, Lee and Schneider defined an executive, found 1,171 men fitting the definition, and compared them with 1,203 non-executives, of whom 563 were women. The comparison covered an average

¹ Lee, R. E., and Schneider, R. F., *J. Amer. med. Ass.*, 1957, 167, 1447.
² Asher, R. A. J., *Brit. med. J.*, 1947, 2, 967.

period of five years and was made on data gathered by taking medical histories and doing physical examinations. These included urine analyses, complete blood counts, chest radiography, and electrocardiography. The results are described as "surprising," for the data revealed "no increase in incidence of either hypertensive or arteriosclerotic disease in the executive class." In fact, arteriosclerotic disease was significantly less frequent among the executives than among the control subjects of comparable age in the same office building. As the authors point out, there are several possible explanations of this, one of them being that success is partly dependent on health, or "the healthier go higher." Again, so far from relaxing when off duty, the executives, owing to their wider interests, are apt to throw themselves into hobbies, and "the benefit that may be derived from such endeavours has been emphasized repeatedly." In the end relaxation may turn out to be about as lethal as too much rest in bed.²

SEEING

"The Emergence of Vision in the Animal World" was the title chosen by Sir Stewart Duke-Elder for the Lister Oration which he delivered earlier this year at the Royal College of Surgeons and which has now been published.¹ The story of how animals came to see is a fascinating one, and no one can speak with greater authority on this subject than the author of *The Eye in Evolution*, which is soon to appear as the first volume of a *System of Ophthalmology*, the successor to Sir Stewart's famous *Textbook of Ophthalmology*.

To most of us seeing is such an important part of our subjective world that it is hard to think of a purposive movement occasioned by light without imagining that the living organism has in some sense perceived the light and reacted accordingly. Without the "perception" of brightness the flower would not grow towards the light. Anyone discussing the emergence of vision must consider light reactions, if not of plants, at least of protozoa, worms, insects, and so on up the animal scale, and must either take some attitude as to "what they really see" or else remain entirely factual and simply describe the stimulus-response patterns observed—denying in the last resort any knowledge of perception in his fellow men. Sir Stewart has taken the more imaginative line, and his descriptions at each stage are illuminated by enlightened speculation as to what the animal might be expected to be "seeing." The first stage of vision is the development of motor taxis, an automatic rigid reaction to light probably not associated with any consciousness. Very primitive animals move to or from a light, insects such as ants and bees move in fixed relation to the sun's rays, and such movements may be built up into complex patterns. In the migration of birds the direction and height of the sun appear to be of great importance, suggestive of a highly developed motor taxis. But it would be unsafe to imply that these were the only sensory cues from which the bee or bird must work out its direction. If we had not got a rudimentary sense of smell the performance of a dog on

the scent would be not merely astounding, it would be incredible. It is hard to know what range of sensory information other animals possess if we lack it entirely.

The second stage of vision is perceiving. This is associated with a brain of sorts and first emerges in worms, which can be trained to respond appropriately to a stimulus in the form of light. In worms there is no image formation, but a new and important feature has arisen. The effect of the light stimulus can be stored in the brain, so that instead of a rigid motor taxis actions may be modified in the light of experience. If it is supposed that such modification of behaviour could not have occurred unless the stimulus was perceived, then perception is to be inferred. This is the stage of vision which ranges from that of the worm to that of the dog. It is specialized for movement, form, and colour with the insect, the octopus, and the vertebrate eyes—all exceedingly different in their development but much the same in their general use.

The final stage Sir Stewart calls "imaginative vision," and it is associated exclusively with the primates. In the same way that the second stage depended upon the beginnings of a brain, so the third stage required the "almost explosive development of the forebrain," with which it was intimately associated. Life in the tree-tops brought some freedom from the swarm of predators on terra firma, but there were severe penalties up there for insecure foothold. Excellent vision and a good sense of space were essential in quick movement among the branches, but animal smells became far off and less important. Man's ancestor left the ground with a nose-brain and four paws: he came down with eye-brain and two hands. And with that brain and those hands he was inquisitive, artistic, and creative. But, as Sir Stewart concludes, "in assessing the potentialities of human progress in the next 10 million years, or indeed of human survival, we must remember the snag that the apes threw sticks and stones while we throw atom bombs."

MULTIPLE SCLEROSIS IN CHILDHOOD

The diagnosis of multiple (or disseminated) sclerosis is essentially clinical, for, though in about two-thirds of cases there are abnormalities in the cerebrospinal fluid, these are not specific for the disease. The clinical diagnosis rests, in relapsing and remitting cases, which form the majority, on the occurrence of episodes of neurological dysfunction at scattered intervals in time. In some cases the symptoms and signs at the onset of the disease suggest widespread lesions, and the clinical diagnosis can then be made with reasonable certainty. Sometimes the initial symptoms and signs point only to a single anatomical lesion, and in this type of case the diagnosis becomes established only when other episodes occur later. Even with a monosymptomatic onset, the pattern of evolution and remission of the neurological disorder may often suggest the diagnosis, though in practice this is rarely made with confidence before adult

⁴ McAlpine, D., and Compston, N. D., *Quart. J. Med.*, 1952, 21, 135.

⁵ Duke-Elder, S., *Ann. roy. Coll. Surg. Engl.*, 1958, 23, 1.

"Cognizance should be taken of the names of closely related substances and where desirable the name should reflect this relationship."

"The names should be distinctive in sound and spelling and should not be liable to confusion with names already in use."

"Names which are difficult to pronounce or remember should be avoided."

"Names used in the *United States Pharmacopoeia*, *New and Nonofficial Remedies (Drugs)*, and *International Non-proprietary Names* should receive preferential consideration."

In giving preferential consideration to existing non-proprietary names, and so avoiding the international confusion which may arise if a second name is adopted for the same drug, the Commission has found it preferable in some instances to accept such a name in spite of its defects. For example, the names chlorotrianisene, diphenylpyraline, and tripeleminamine were issued by the American Medical Association and widely used before the drugs were sold in Britain. Although the Commission was critical of these names, the balance of advantage lay in accepting them as Approved Names.

3. The Report states (para. 43) that "at present a year or two may elapse before an approved name is formulated for a new drug. During this period doctors get into the habit of prescribing the new preparations by their trade names . . ."

It is exceptional for a long period to elapse between the appearance of a new drug on the English market and the publication of an Approved Name. Approved Names for new drugs of English origin are usually available by the time the drug is placed on sale and indeed the Approved Name is generally available before the drug is distributed.

During the past five years, nearly 60,000 copies of lists of Approved Names have been circulated by the Commission, but wide advertisement is the most potent factor in establishing the names of medicinal products and it is manifestly not a function of the Commission to advertise Approved Names in the manner or on the scale adopted for trade names. Copies of supplementary lists of Approved Names are supplied to some hundreds of correspondents at home and abroad and they are published in many professional journals.

4. The Committee states in para. 46 of its Report that "we consider also that before putting a new drug on the market manufacturers should be encouraged to ask the British Pharmacopoeia Commission to give it an Approved Name. As soon as that has been done, the approved name should appear on labels and advertising literature for proprietary preparations as prominently as the trade one."

Over many years it has been the practice of most British manufacturers to approach the Commission for an Approved Name for a new drug before placing it on the market. For such products the Approved Name is usually available whilst the substance is undergoing trials and before it is generally released for sale. The Commission has no control over the manner in which Approved Names are used by manufacturers on labels and in advertising literature.

5. The Committee expresses the opinion (para. 44) that "some of the principles of nomenclature now in force may well be inappropriate to-day," and recommends that the Commission be asked to review these principles. It is difficult to comply with this request unless a more specific statement is provided.

The Report makes no reference to a number of important considerations that apply in the selection of Approved Names, such as the international aspects including the non-proprietary names issued by the World Health Organization, and by the American Medical Association for many drugs that appear in England only after a period of use in the United States. Indeed, most drugs introduced on the English market have had a period of use in the United States or elsewhere in association with a non-proprietary name, and unless overriding considerations apply it is undesirable to coin a second non-proprietary name even when the estab-

(Continued at foot of next column)

To-day's Drugs

In this column we publish from time to time authoritative notes on a selection of drugs in current use.

Glyped (Imperial Chemical Industries Ltd.).—This contains 25% glyceryl triacetate in an emollient cream base. It is recommended for skin infections due to fungi, particularly tinea pedis and tinea cruris. The active principle in this preparation is claimed to be the free acetic acid which is liberated with glycerol in the skin when esterase, an enzyme present in the skin itself, hydrolyses the glyceryl triacetate. The amount of acid thus liberated is automatically controlled, since the enzyme esterase is deactivated when the acid reaches a certain concentration and recovers its activity when the acid becomes sufficiently diluted by diffusion through the tissues.

No untoward reactions resulting from the therapeutic use of this substance have so far been reported, and it appears to be effective in treating those infections which respond well also to other widely used preparations—for instance, tinea pedis infections due to *Trichophyton mentagrophytes* and *Epidermophyton floccosum*, and tinea capitis due to *Microsporum canis*. It is not so effective in tinea pedis due to *T. rubrum*, and is ineffective in candida infections ("moniliasis") of the skin.

N.H.S. basic price: 25-g. tube, 3s. 11d.

Sytron (Parke, Davis and Co. Ltd.).—This is a cherry-flavoured syrup containing 380 mg. of sodium ironedetate (iron chelate of monosodium ethylenediaminetetra-acetic acid), equivalent to 55 mg. of iron in 8 ml. It is recommended for the treatment of iron-deficiency anaemia in doses of 2 teaspoonfuls thrice daily after meals, children according to age receiving $\frac{1}{2}$ –1 teaspoonful.

There are two indications for the use of this preparation by patients who need to take iron in a liquid form: (1) it is pleasantly coloured and flavoured and might be acceptable to those few who "cannot take iron"; and (2) it is more suitable for those patients in whom other oral iron preparations produce intractable constipation. This substance produces diarrhoea in about 25% of patients treated with it—more commonly than with other iron preparations. In a few patients it produces a satisfactory laxative effect.

N.H.S. basic price: 16 fl. oz., 15s. 7½d.

(Continued from preceding column)

lished name falls short of the Commission's desideratum. Approved Names are applied not only, and primarily, in the writing of prescriptions but also in scientific articles appearing in journals with world-wide readership, for reference purposes, and in the labelling of products in accordance with legal requirements including purchase tax and poisons regulations. Approved Names are also of great value in indicating to prescribers and pharmacists that the same drug is being described under more than one trade name. Attention is also drawn to the problems which arise in relation to existing names, especially those registered as trade marks. It has been a frequent experience that a proposal for what would appear to be an admirable short name must be discarded in favour of a more complicated one because, on the authoritative advice received by the Commission from the Patent Office, the short name is held to conflict with a trade mark registered in this country.

The Commission offers this statement in the hope that it may dispel any misunderstanding which the Report may have created, and that it may help towards a better appreciation of the origins and purposes of Approved Names.

D. M. DUNLOP,
Chairman.

T. C. DENSTON,

Secretary,
British Pharmacopoeia Commission, 1953-8.

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Annual Meeting of Royal College of Surgeons of England

SIR,—I am grateful to you for allowing me to use this opportunity of bringing to the notice of the profession that the College is holding its Annual Meeting this year on September 26 and 27 in Cardiff. As you know, the College has recently adopted the policy of holding meetings from time to time in provincial centres, and the first of these was held in Manchester in 1955. The purpose of the Council in holding these meetings is to bring the College closer to its provincial Fellows and Members and to enable them to take part in some of its activities. The Council is particularly anxious that Members of the College shall join us at this meeting, and any other diplomates will of course be very welcome. Fellows have already been notified individually. The meeting will consist of a reception at Cardiff Castle, kindly given by the Lord Mayor and Council of Cardiff, and a subscription dinner, both on Friday, September 26. Tickets for the dinner (two guineas each) and tember 26. Tickets for the dinner (two guineas each) and the invitations for the reception can be obtained from the Secretariat of the College, but the numbers for both events are limited and early application is necessary. On Saturday, September 27, the morning will be devoted to scientific exhibitions and surgical operations arranged by a fork mittee at the Cardiff Royal Infirmary, followed by a fork lunch, kindly given by the Board of Governors of the United Cardiff Hospitals. In the afternoon, at 2.30 p.m., the statutory annual meeting of Fellows and Members will be held in the Reardon Smith Hall, and this will be followed by the conferment of the Honorary Fellowship of the College on Sir Russell Brain, Bt., who will afterwards deliver a lecture on "The Cervical Spine."

The Council hopes that this meeting will prove to be as successful an event as was the meeting in Manchester, and we trust that our colleagues in Wales will make a special effort to attend.—I am, etc.,

J. PATERSON ROSS,

President,

Royal College of Surgeons of England.

Prevention of Lung Cancer

SIR,—I would like to support Dr. E. R. Nye (*Journal*, August 9, p. 389) in his suggestion that a campaign should be especially directed to children and young adults. With this end in view, the Central Council for Health Education has already distributed 171,800 leaflets to local authorities for use in schools as well as 84 sets of display material also designed to appeal to the older schoolchild, and over two million bookmarks for use in public libraries. We have evidence of great interest in this topic in schools, and several meetings of head teachers have been organized, some of them being addressed by medical officers of health and others by a member of the Central Council for Health Education staff.

The subject of smoking is highly charged with emotion and involves an underlying motivation of some complexity. This means that fear of cancer alone will not necessarily cause a change of attitude towards the habit. These factors must be taken into account in the personal and direct educational efforts which are required to supplement the publicity already referred to. The fundamental questions are: At what age do young people start smoking and why? The latter is answered in part by the tobacco advertisers themselves. The prestige motive, and personal identification with an admired figure, either real or fantasy, characterizes all such advertising to-day.

All this confirms the teenager in his belief that the non-smoker is the odd man out. Part of our task, therefore, is

to create a public opinion which discounts the importance of smoking as a condition of social acceptability, as well as discrediting the popular assumptions that tobacco has a therapeutic effect. A good deal of research would be necessary before we can achieve this aim, but a promising start has been made in the U.S.A.¹

With reference to Dr. Nye's remarks about middle-aged men who are "almost beyond redemption," it should be remembered that Doll and Bradford Hill² showed, in a study of 40,000 medical men and women, that the mortality from lung cancer amongst smokers was three times that amongst men who had given up the habit more than 10 years previously. The average ages of these two groups were 44 and 42 respectively, which suggests that men in the late twenties and early thirties still have a chance of avoiding lung cancer during the next 10 years. This is additional justification for a campaign directed to the public at large, and we should not allow the idea to become prevalent that a number of middle-aged men who have smoked heavily all their lives could not still benefit from the effect of giving it up.—I am, etc.,

A. J. DALZELL-WARD,

Medical Director,

Central Council for Health Education.

Anorexia Nervosa

SIR,—Much of what we know on the subject of anorexia nervosa came from Guy's Hospital, yet Dr. D. Stafford Clark's letter (*Journal*, August 16, p. 446) is disappointingly carping and non-contributory. In his first sentence he derides my limited penmanship, in his second he shows pique at my choice of title, and in his third introduces wide and intangible issues which are altogether irrelevant. But in dealing with the treatment of anorexia nervosa his letter illustrates some points which deserve further comment. According to his chart, nine of his thirteen patients were discharged while still under 8 st. (50.8 kg.) in weight—yet he blithely admits that the total average time in hospital per patient was five months. One was detained for eight months and another for ten months. Surely this almost amounts to a study of the natural history of the disease and is no cause for complacency over the merits of psychotherapy any more than it extols the salubrious air of the York Clinic. And what of the patient (Case 1) who was discharged weighing only 5 st. 13 lb. (37.6 kg.)? Had he nothing more to offer and does he not accept the possibility that she may have died or gone elsewhere? Is Dr. Stafford-Clark so completely reassured that because "readmission is always available . . . there is no reason to assume an unfavourable result . . ."? In patients of this nature who are slowly committing suicide are we to stand by with hands behind our backs lest we be accused of "assault upon the patient"?

The act of intubation, according to Drs. M. Sim and R. W. Tibbetts (*Journal*, August 16, p. 447), is an expression of sadism by the doctor in response to the patient's over-determined masochism. But was Ryle a sadist to perfect his tube, and are we all guilty of a sinister duality of purpose when we show interest in the acid content of the stomach? In expressing horror at the thought of introducing food by this method Dr. Stafford-Clark, Dr. Sim, and Dr. Tibbetts show remarkable ignorance of modern day-to-day medical and surgical practice. Admittedly some of the seven patients in my series at first objected. The game, after all, was up. But their objections were overcome not with physical violence but with verbal persuasion, sometimes gentle, sometimes firm. The tube was invariably introduced by a member of the nursing staff on the conscious patient in the presence of twenty-seven others, not forcibly under barbiturate narcosis by a pack of purposeful warders in the seclusion of an observation ward. One was perverse (Case 14) and removed the tube on the first occasion, submitting finally only when offered psychiatric treatment as an alternative. But can this violent reaction against intubation

before fair trial be entirely due to timidity—surely it does not stem from covetousness?

In conclusion, and at the risk once more of being tendentious, of course anorexia nervosa is initially psychogenic, but its symptoms are aggravated and others develop as a result of malnutrition. With renourishment and on return of physical well-being so may these symptoms sometimes disappear, and the most elegant way to achieve renourishment is by intubation. If Dr. Stafford-Clark must have his unifying principle it is that reassurance, encouragement, explanation, and other expressions of kindness are expected of us in our relationship with all patients we are privileged to treat. Usually this goes without saying and in the case of anorexia nervosa it has been said so many times before.—I am, etc.,

London, E.1.

EIRIAN WILLIAMS.

Treatment of Asthma

SIR,—In the *Journal* of May 17 (p. 1166) there was a leading article on "Steroids in Treatment of Asthma." On the bottom of the page, left-hand column, was the statement, "But deaths from asthma suddenly increased in 1951 by nearly one-half, and this increase has been maintained.

This is the period when steroid therapy had been in vogue." From the accompanying graph of deaths from asthma, together with the deaths from bronchitis and pneumonia, England and Wales, taken from the Registrar-General's figures, it can be seen that there was indeed an increase in the deaths from asthma in 1951, which was accompanied by an increase in the death rates from bronchitis and pneumonia, but that since then there has been a marked fall in the death rate from asthma. This conflicts with the statement that "... this increase has been maintained." Your writer states, "There is no proof that steroid therapy is the cause of the sudden rise, but the figures are alarming."

I agree with your writer that "steroid therapy is undoubtedly a most valuable method of treatment for severe chronic asthma and status asthmaticus" and I regret what appears to me to be a misstatement and the suggestion that steroid therapy may possibly have caused this increase. The suggestion from this graph to me is that steroid therapy may possibly have been responsible for the reduction in the number of deaths, but it is as yet too soon to form any conclusions.—I am, etc.,

Llandaff, Cardiff.

D. A. WILLIAMS.

SIR,—As the co-author of a paper¹ on the value of "asmapax" in the treatment of asthma, I was interested to read your notes in "To-day's Drugs" concerning this product (*Journal*, June 28, p. 1541). The writer of this note does not seem to appreciate that ephedrine in a resin-bonded form has a sustained 12-hour action. When he states that

ephedrine in a resin-bonded form may prolong the total duration of action he is incorrect. The operative word should be "does." Various papers¹⁻⁷ reporting the chemical and laboratory evidence to support this statement have appeared recently in the medical press. The writer also states, "Bromvaletone is included presumably for its sedative action. . . ." As bromvaletone is a sedative and hypnotic, and has no other action, the reason for its inclusion in asmapax would seem to need no qualification. Furthermore, asmapax in my experience is the only available sustained action drug for the treatment of asthma. If taken regularly as reported in the paper¹ already mentioned, asmapax is more of a curative drug and too useful to be considered only, as the writer of these notes remarks, as yet another combination of antispasmodic and sedative drugs intended for the symptomatic treatment of this disease.—I am, etc.,

Birmingham, 18.

Prevention of Rheumatic Fever Recurrences

SIR,—Professor E. G. L. Bywaters and Dr. G. T. Thomas (*Journal*, August 9, p. 350) discuss the use of penicillin preparations for the prophylaxis of recurrences of rheumatic fever. This article stated, "Injections of benzathine penicillin have been advocated by some as preferable to penicillin by mouth. Though this method ensures that prophylaxis is carried out, it is difficult to impose a regime of weekly injections on children in the knowledge that this must be continued for years." The authors then go on to quote, in part, from the further report of the Rheumatic Fever Committee of the Royal College of Physicians, 1957.

This might lead some readers to assume that weekly injections were recommended by that Committee, but this is not so. The actual wording of the appendix dealing with prophylactic use of benzathine penicillin is as follows:

(iii) If for any reason oral prophylaxis cannot be given over a particular period, an intramuscular injection of 1.5 mega units (5 cc.) of benzathine penicillin will protect the child for one month.

To underline this recommendation for monthly or, at most, fortnightly injections, the second report of the Expert Committee on Rheumatic Diseases of the World Health Organization speaks in this way.¹ "Prophylaxis with penicillin by mouth (100,000–200,000 units of benzylpenicillin twice a day) or by injection (1,200,000 units of benzathine penicillin intramuscularly once a month) has proved somewhat more effective than prophylaxis with sulphonamides." The appendix on prophylaxis with benzathine penicillin from the same report (Annex 3, page 27) recommends benzathine penicillin 1,200,000 units once a month or 600,000 units twice a month.—I am, etc.,

Haemorrhage from Superficial Varix

SIR,—Whilst agreeing with the sentiments of Mr. W. W. Woodward (*Journal*, July 19, p. 166) in deploring casual reassurance of the varicose vein sufferer against the chances of a varicosity bleeding, I must point out that the first-aid treatment by direct pressure which he recommends is neither the simplest nor the most efficient. Surely the teaching is that the first step in the treatment of venous haemorrhage is elevation of the part. My letter is prompted by an enlightening experience I had shortly after qualifying which

proved to me very forcibly that treatment by direct pressure alone could end in a fatality.

In the middle of a public lecture I was attending I suddenly heard a sound as if a tap had been turned on and water was running on to the wooden floor. There followed the sound of someone getting up a few rows behind and leaving the hall, whereupon the sounds mentioned ceased. Even when, shortly afterwards, the famous call for "a doctor in the house" was made, I was unable to connect the incidents. Noticing a crowd gathering outside the door at the back of the hall, I shyly crept out. A man of about 40 was sitting in a chair surrounded by a pool of blood. He was extremely pale and quite unconscious, being only retained on the chair by the efforts of a friend. Persevering, if probably inexperienced, attempts at first-aid were being applied in the form of local pressure over a bleeding varicosity. But the haemorrhage, although abated, was obviously continuing. Against the protests of the friend I got the unconscious man off the chair on to the bloody floor, and lifted the bleeding leg in the air. I was as relieved as the onlookers to see that this treatment produced an immediate cessation of the haemorrhage, rapidly followed by a return of the patient to consciousness.

I therefore suggest to Mr. Woodward that the best advice to give to a patient with vulnerable varicosities is not to lie apply pressure directly to the bleeding point but to lie down and lift the leg up in the air. This instruction is probably more easily remembered, tainting of the bizarre, and also considerably more easily executed if the patient happens to be alone. I might add that this instruction should also be given to every patient undergoing an out-patient operation involving ligation of varicose veins, as the haemorrhage from a slipped ligature can be equally catastrophic.—I am, etc.,

D. G. CHAMBERS.

Nicosia, Cyprus.

A New Syndrome in Alcoholics

SIR,—Your annotation (*Journal*, August 2, p. 297) discusses Dr. L. Zieve's report¹ on a heretofore unrecognized syndrome associated with alcoholic fatty liver and cirrhosis, with jaundice, hyperlipaemia, and haemolytic anaemia as the essential features (features, incidentally, sometimes also seen in cases of viral hepatitis in the recovery phase). The illness is reported to improve rapidly once the drinking stops, hyperbilirubinaemia and hypercholesterolaemia receding over a few weeks. Hepatic function, "usually mildly disturbed" in this syndrome, "improves rapidly."

That disturbances of liver function in alcoholics are often reversible in nature is also evident from results of studies of blood chemistry carried out as a routine procedure in of about 350 patients of Warlingham Park Hospital. Though there was only rarely clinical evidence of liver damage, approximately half of these patients showed, on admission to hospital, an abnormality in at least one test out of a battery of five different tests. Most patients showed abnormalities in several tests, though each test by itself had abnormal results in a minority of patients only. Most often positive was the bromsulphthalein clearance test—i.e., in one-third of the 66 cases in whom it was carried out—and of those patients in whom the battery of tests also included the B.S.P. clearance test, three-quarters showed abnormal results in at least one test. On retesting the 350 patients about six weeks later after a period of abstinence (and on a vitamin-supplemented full diet) the results of these tests were markedly improved, incidentally, was portion of cases. Similar improvement, incidentally, was often noted in blood pyruvate and co-carboxylase tests.

However, neither alcoholics admitted to mental hospitals in this country² nor those forming the basis for Dr. Zieve's report can be considered a representative sample of a total population of alcoholics. For example, cirrhosis of the liver is said not to occur in more than 8% of "chronic alcoholics,"³ but was detected by liver biopsy in 15 of Dr. Zieve's 20 patients. Jaundice was present in every one of Dr. Zieve's patients, but must be rare in an unselected sample of alcoholics. No case of jaundice was seen among the patients admitted to the Warlingham Park Hospital alcoholic unit, though hyperbilirubinaemia (above 0.5 mg.%) was found in 6.5%, and a positive Schlesinger's test obtained in one-third

of these patients on admission (in 10% this reaction was still positive six weeks later). Cholesterol elevation above 500 mg. per 100 ml. was observed in three-fifths of Dr. Zieve's patients. Among 350 Warlingham Park Hospital alcoholics, approximately 15% showed on admission a low blood cholesterol (below 150 mg.%), 7.7% a high blood cholesterol (above 250 mg.%). As a further 3.4% showed high values in subsequent tests, a total of 11.1% showed hypercholesterolaemia at some time of their hospital stay, in no case, however, reaching a level of 400 mg.%.

The patients forming the basis for Dr. Zieve's report were therefore quite different in many respects from the ones admitted to Warlingham Park Hospital, and no generalizations are possible from such selected samples to conditions in "alcoholics" in general.

While, as your annotation says, "all physicians" are acquainted with the occurrence of liver cirrhosis in alcoholics, it seems unfortunately much less widely appreciated that clinical evidence of liver disease—such as that shown by Dr. Zieve's patients—probably occurs in a minority of alcoholics only and in these only in late phases of the disorder. Among the Warlingham Park Hospital alcoholics two-thirds had at one time or another in the past sought medical advice for physical symptoms associated with their drinking, for the first time at an average age of about 40 years: approximately 10 years after there had first appeared other indications of incipient alcoholism in these patients. Obviously a sample of alcoholics admitted to general hospitals in this country will probably contain a higher proportion of people with definite physical abnormalities. But the emphasis laid, in the teaching of medical students and in the medical press, on the complications of alcoholism rather than on its earlier and essential phases, and the interest shown in new syndromes, however justifiable and important, should not obscure the fact that alcoholism could and should be diagnosed in its early stages and that treatment should be strongly advised long before there is clinical evidence of irreversible physical or mental complications. We acknowledge gratefully the technical work done by Mr. L. G. Coates, Warlingham Park Hospital Laboratory, and the staff of the Mental Hospitals Group Laboratory, Epsom.—We are, etc.,

Contraception by Inhibition of Ovulation

SIR,—Your annotation (*Journal*, August 2, p. 297) reports favourably on the use of "enavid" as an oral contraceptive, hailing this as "a remarkable step forward." The annotation makes no mention of harm to the foetus should pregnancy result despite the tablet.

It is known (Thiersch¹) that "aminopterin," a drug which has been experimented with as a contraceptive, has in fact produced malformed foetuses. Further, your annotation (*Journal*, July 26, p. 218) refers to foetal malformations produced by progesterone, the substance which was the starting point for the use of enavid and which presumably has a similar action.

Although the compound is described as harmless and "various clinico-pathological investigations brought no undesirable effects to light," it is surely unwise to permit the marketing and widespread use of such potent compounds for this purpose. Careful studies of the effects of doses which fail to prevent pregnancy on the foetus and of the long-term effect of repeated dosage over several years on experimental animals may yet reveal serious ill effects. The use of these tablets in a field trial is not a therapeutic measure although the participants are described as "patients." Such an innovation has very important social implications. Doubts which may be felt as to its permissibility are reinforced by the choice of Puerto Rico as a site for the trial.

A contraceptive "pill" should not be regarded as a cheap substitute for the radical and costly improvement of the standard of living of the underdeveloped countries which is essential for the health of the new generation.—I am, etc.,

London, S.W.17.

Complication of Pertussis Immunization

SIR,—In view of the recent correspondence about reactions to immunization against whooping-cough, I feel I should record the two following cases, which occurred within a month or two of each other last year.

Case 1.—A girl of 9 months old, an adopted child, was given her first injection of combined diphtheria/pertussis vaccine. Twenty-four hours later she became feverish, showed signs of cerebral irritation and was admitted to hospital with convulsions. There all investigations proved negative, and after a few days of heavy sedation she made a complete recovery.

Case 2.—Twins, a boy and girl 10 months old, were given 1 ml. each of the triple antigen at 11 a.m. At 6 p.m. the girl became feverish, at 7 p.m. she started to get convulsions and was admitted to hospital early the next morning. Once again all investigations proved negative, but she was seriously ill for several days, having to be kept heavily sedated for over a week, and it was several weeks before she got back to normal. The boy had no reaction whatsoever.

The bottle of antigen was sent to the makers for thorough testing, but it proved to be absolutely satisfactory.—I am, etc.,

Tavistock.

T. M. DAVIE.

Reduction of Fracture-dislocation of Hip-joint

SIR,—I read Mr. D. S. Murray's paper (*Journal*, August 16, p. 427) with great interest and should like to congratulate him on his successes in these two patients. Two years ago I was faced with a similar problem, when a 19-year-old Indian seaman fell 30 feet (9.2 m.) into a ship's hold, and, besides severe injuries to both wrists and elbows and skull, there was a posterior dislocation of the right hip-joint with a transverse midshaft fracture of the right femur, compound from within. Antero-posterior transfixion of the right greater trochanter by a stout Steinmann's pin, as recommended by Ingram and Turner,¹ enabled the dislocation to be reduced surprisingly easily (as Mr. Murray also found). In this patient the Steinmann's pin was grasped by both hands and no other mechanical aid was used. Mr. Murray advocates the help of two assistants for this manoeuvre; in this patient no assistants were available other than an excellent theatre sister. A Kuntscher nail was passed down the femoral shaft immediately after this reduction. Almost two years later the patient has full function of the right hip and knee (personal communication from Mr. S. R. Chandra in Calcutta).—I am, etc.,

Salford.

Bacteria in Antiseptic Solutions

SIR,—I read your annotation (*Journal*, August 16, p. 436) on bacteria in antiseptic solutions with great interest, and I am very much surprised that you should conclude that, because of the cases cited, "zephiran" and the other quaternary ammonium compounds are unsuitable for some of the uses to which they are put. The series of *Pseudomonas pyocyanea* bacteriaemias caused by swabs stored in zephiran demonstrates one of the well-known properties of this antiseptic—i.e., that it is adsorbed on to textiles. This property, of course, makes zephiran an ideal agent for sterilizing hospital linen and babies' napkins. However, this attribute makes the technique of storing swabs in such a solution and then using the same solution for skin sterilization an

unsatisfactory one. The zephiran from the solution is adsorbed on to the cotton-wool and therefore the concentration of disinfectant in the solution is lowered to an ineffective level, especially to the most resistant of organisms—that is, *Pseudomonas pyocyanea*. This does not make the quaternaries unsuitable for skin sterilization. If a fresh tincture (which has not been left in contact with textiles) is used, effective skin sterilization is achieved.¹ The recommendations for the use of zephiran take all these factors into account. Thus I think that the proper conclusion should be that in performing sterilization procedures careful attention to technique is important whether quaternaries or any other means, such as the autoclave, are used.—I am, etc.,

Misleading Urine Tests

SIR,—Dr. A. Phillips has drawn attention (*Journal*, August 16, p. 448) to one of the few fallacies in the use of the enzyme test strips for urine glucose, namely external contamination with hydrogen peroxide.¹ In a similar fashion, hypochlorites (and household cleansers which contain them) can produce false-positive reactions.¹ Other alleged false-positive reactions referred to this laboratory have proved to be due to the presence of glucose in amounts too small to be detected by Benedict's and similar tests, and no substance occurring naturally in urine has yet been reported as giving a false-positive result. The possibility of contamination of the container by peroxides or hypochlorites (or, indeed, by glucose) must always be remembered.—I am, etc.,

Edinburgh.

Nuclear Sexing

SIR,—Nuclear sexing is a well-established laboratory aid in the diagnosis of sex. The expectations of Moore, Graham, and Barr¹ have been fulfilled. I suspect that full use is not being made of the method in cases where the external genitalia are found to be abnormal at birth. A small piece of amnion placed in surgical spirit (or 95% alcohol) for a few hours provides excellent material for nuclear sexing. It can be stained and examined as a whole mount.

Experience has shown that, in the newborn, it is little better than guessing to attempt to distinguish, by external examination alone, between apparent females with masculine features (enlarged clitoris, etc.) and apparent males with any degree of hypospadias—testes being impalpable. Yet a diagnosis of the sex must be made. The first step in the diagnosis of these difficult and potentially tragic cases should be the preservation of a little piece of amnion in spirit. The nuclear sex could be determined within 24 hours and would probably ensure that the appropriate sex for the child was announced.—I am, etc.,

Electrified

SIR,—With regard to the letter from Mr. Lionel H. Pimm and the electric shock he received from a patient (*Journal*, August 9, p. 390), I had a similar experience last year. I was asked to see a patient in bed and he was said to be suffering from influenza. I took his pulse and I was immediately aware of an electric current passing between us. I thought it queer, but said nothing and completed my examination. I then returned to the matter of the electric current, and, on lifting the lower bedclothes, I found his feet

resting on an electric pad, switched on and with imperfect insulation and earthing. Could Mr. Pimm's case have been due to some freak of improper earthing of electrical apparatus?—I am, etc.,

Birmingham, 23.

E. LEWIS BUTLER.

Iron Preparations

SIR,—Dr. C. F. Herridge's comparison of liquid preparations of an iron chelate—ferrous gluconate and ferrous succinate—(*Journal*, July 19, p. 140) was of particular interest as we recently conducted a clinical trial at Saint Mary's Hospitals of another iron chelate—ferrous aminoacetosulphate—in tablet form. This compound has already had promising trials in other countries.^{1,2,3} Fifty pregnant women with iron-deficiency anaemia were treated for at least six weeks with a surprising lack of side-effects. There was no diarrhoea or other gastrointestinal disturbance, although a few patients complained of headache. The haemoglobin levels of patients treated with the chelate rose nearly twice as fast during the first two weeks of treatment compared with a similar group of women treated with an equivalent amount of iron as ferrous gluconate. The haemoglobin levels were also higher in the chelate-treated group at the end of treatment. Full details of this investigation are being published.

Dr. Stuart Carne (*Journal*, August 9, p. 388) draws attention to the relative cost of iron preparations. During our clinical trial we considered the relative costs of treatment and a pricing bureau of the Joint Pricing Committee for England was asked to give the basic and gross costs of various iron preparations in tablet form. The following figures were given.

	Fe per Tablet mg.	Basic N.H.S. Price	Gross Cost to N.H.S.
		s. d.	s. d.
"Fersolate"	60	1 5	1 10
Ferrous gluconate (B.N.F.)	35	1 9	3 6*
"Plesmet"	50	2 8	4 8
"Plesmet"	35	3 8	5 11
"Fergon"	35	3 11	6 2
"Ferromyn"	25	11 11	16 2
"Rarical"			

All prices per 100 tablets.

* Average price—the prices of individual manufacturers vary considerably.

As will be seen, there is an enormous price difference and the advantages claimed for the more expensive preparations hardly justify their greatly increased cost. Plesmet was the brand of ferrous aminoacetosulphate used in our trial, and, although more expensive than the iron preparations we use routinely, appears to be the cheapest chelated form of iron on the market, judging from the advertisements in the medical press.—I am, etc.,

Beds for the Aged

SIR,—Few would argue with Dr. Arnold B. Cowan's estimation of the need of the elderly for hospital treatment or find his criticism of the existing facilities over-severe (*Journal*, August 2, p. 325). The allocation of more beds for the hospital care of the aged would be only a short-term answer to the problem, unless these beds were properly staffed by nurses, doctors, and ancillary staff. Without proper staffing they would become long-stay beds and individuals admitted to them might become long-stay cases, unfit to return to independence outside hospital or even to enter such sheltered accommodation as a welfare authority hostel. Anyone with experience in this aspect of hospital work knows how tragically easy it is for this to happen.

The problem can be solved not by more beds but by more activity of the existing beds. There are too many inactive beds for the aged in this country and too few properly

trained physicians with the necessary foresight to see what opportunities for the practice of clinical medicine and for research exist for anyone taking clinical charge of hospital beds set aside for the care of the aged. The late Dr. O. Olbrich has left us at Sunderland, Co. Durham, a fine example of what can be done with "An Institution for the Care of the Chronic Sick."—I am, etc.,

Oldham, Lancs.

W. H. LLOYD.

Coudé Catheter

SIR,—I am sorry that Mr. Hamilton Bailey, Mr. W. J. Bishop, and Mr. A. Clifford Morson were dragged so deeply into the mire (*Journal*, August 23, p. 513). Perhaps a perusal of previous issues of *The Lancet* might have made clear the satirical intent of the article on Coudé.

Volume 4, No. 4, contained notes on the lives of Johannes Haemolyticus, or Giovanni Emolitico (1678–1726), and *Staphylococcus* of Alexandria (c. 273–200 B.C.), whose names were said to be enshrined in *Streptococcus haemolyticus pyogenes* and *Staphylococcus aureus*. It is to be hoped that these did not lead to similar confusion among bacteriological historians.—I am, etc.,

Newport, Mon.

PETER BIRKETT,
Formerly Editor, *The Lancet*.

Gluten-free Diets

SIR,—I read with interest the article on "gluten-free diets" by Dr. A. F. Fletcher and Miss Majorie McCricker (*Journal*, August 2, p. 299). As I have been preparing such a diet for my 4-year-old daughter for the past 18 months, I feel the following additions to the list of gluten-free products might be useful to others as well. *Meltis Ltd.*—fudge, new berry fruits, orchard fruits; not turkish delight. *Oxo Ltd.*—oxo fluid (bottles), oxo concentrate (jars); not oxo cubes. *Wilts United Dairies Ltd.*—ice cream mix. *S. Parkinson and Son*—fruit drops, barley sugar, butter-scotch. *Nairn's Oatcakes Bakery*—oatcakes. *Batchelor's Peas Ltd.*—processed and garden peas, baked beans, butter beans, packet peas and fruits; not canned soups or soup mixes. *Lunham Brothers Ltd.*—spam. *Joseph Terry and Sons*—block chocolate, i.e., bitter Oliver Twist and the Devon range neapolitans; not pastilles or crystamints or Easter eggs. *J. S. Fry*—Easter eggs.—I am, etc.,

Salisbury, Wilts.

MOYRA TYRRELL.

X-ray Record Cards

SIR,—In her paper to the Section of Social and Preventive Medicine at this year's B.M.A. Annual Meeting at Birmingham, Dr. Alice Stewart mentioned the difficulty that she and her co-workers experienced in assessing the number of radiographs a particular patient had had taken. Apparently patients' memories are quite unreliable, while case-sheets do not always help, since many patients attend a number of different hospitals and clinics in their lifetime. In the discussion which followed Dr. Stewart's paper I suggested the possibility of issuing personal x-ray record cards to be produced whenever the patient attends an x-ray department.

In its simplest form this would merely give the date, the patient's name and address, with a space for changes of address, date of birth, name of hospital or clinic, type of examination, and the number of films taken (plus the screening time where applicable). Printed on the card would be an instruction to the patient to take it whenever attending a hospital or clinic. In this way not only could the total radiological picture for a large number of patients be built up for future reference, but it would also obviate at a glance unnecessary repeats of procedures already carried out at another hospital or clinic only a short time before. I realize that many people would lose or forget their cards, but a large number (probably the majority) would not. In any case I think the scheme is worth a try. Perhaps a start could be made with the under-forties.—I am, etc.,

Liverpool, 18.

MYER GOLDMAN.

Obituary

CHEVALIER JACKSON, M.D., F.A.C.S.

Dr. Chevalier Jackson, renowned for his work in developing bronchoscopy, died on August 16 in the Temple University Hospital, Philadelphia. He was 92 years of age.

Chevalier Jackson, who was born in Pittsburgh on November 4, 1865, graduated in medicine from Jefferson Medical College in Philadelphia in 1886. Deciding from the beginning of his career to specialize in oto-rhino-laryngology, he became professor of laryngology at the University of Pittsburgh in 1912. Four years later he moved to Jefferson Medical College, where he was first professor of laryngology and later professor of bronchoscopy and oesophagoscopy. Retiring from this appointment in 1930, he remained professor of clinical bronchoscopy at Temple University School of Medicine for a few more years before finally retiring from his teaching posts.

An Honorary Fellow of the Royal Society of Medicine, Chevalier Jackson was honoured by medical organizations all over the world. By the American Medical Association he was awarded the Distinguished Service Medal and Citation in 1940, and he was decorated by several foreign governments.

His son, Dr. Chevalier L. Jackson, went into the same specialty as his father, and is now professor of laryngology and broncho-oesophagology at Temple University Medical School.

We are indebted to Mr. MAXWELL ELLIS for the following appreciation: Safe and routine bronchoscopy and oesophagoscopy are entirely due to Chevalier Jackson. When he first became interested in the subject, nearly seventy years ago, peroral endoscopy was very rarely performed, and then only by one or two extremely courageous and skilful men in Germany and Austria. The instruments were very large and bulky, and there was a definite operative mortality. Pictures in old books illustrating the technique are quite frightening, and it seems impossible to believe that patients would voluntarily submit themselves to this medical form of sword-swallowing. Dr. Chevalier Jackson brought to bear upon the subject a powerful intellect, a gift for mechanical invention, and an untiring and devoted proslitism. There could have been no more single-minded man in the history of medicine. He sighted his goal early in life; he moved towards it unerringly and steadily for over half a century; and in the end he saw his work become an integral part of the practice of medicine.

At the beginning of his career he tooled most of his own instruments, oesophagoscopes in 1890 and bronchoscopes and laryngoscopes 10 years later. Gradually the ponderous instruments used by Killian and Brünings became streamlined into those which most people outside Central Europe still use to-day. Jackson's great technical contributions were the introduction of distal illumination, adapted from the cystoscope, a general lightening of the structure of the tube as well as a reduction in its lumen, and the invention of numerous patterns of forceps to suit the many problems of foreign-body removal which at first chiefly engaged his attention.

In his early days at Pittsburgh he was one of the first physicians to buy an automobile, and in this primitive vehicle, as we would nowadays view it, and with his instruments, almost equally primitive by modern standards, he would undertake any journey in any weather to a patient or to a medical meeting. These early struggles took their toll of his health, and he developed tuberculosis. However, this only served as a spur to his overriding and almost obsessional belief in what he conceived to be his mission, and whilst supposed to be resting in bed he prepared the drafts of his earliest books, historical classics still full of ideas and information. In 1907, *Tracheo-Bronchoscopy, Endoscopy and Gastroscopy* appeared, dedicated to Killian, putting on record the conception of peroral endoscopy as we know it to-day. In 1914, after a second attack of tuberculosis, *Peroral Endoscopy and Laryngeal Surgery* followed, with its clear descriptions of techniques and instruments, and also of the type of training which he considered essential. In addition to technique, this book included a fuller account of many diseases already known and some brought to light for the first time by this means of direct observation. It can rarely be said of a single individual that any discovery was his alone, and this cannot be said of Jackson, as peroral endoscopy had been practised by others before him. But it was certainly his achievement to have made this examination so completely safe that it is now a normal technique acquired by every chest physician and surgeon and laryngologist in the world. Much of Jackson's achievement was made possible by the predilection of American children and adults to inhale or swallow foreign bodies. It seems almost impossible to believe that the work which gained him the Bok prize in 1927 (awarded to the most distinguished Philadelphian citizen) was based on the successful removal of over a thousand foreign bodies of various sorts, sizes, and shapes. Jackson initiated many campaigns trying to educate parents to prevent children inhaling foreign bodies, and he spoke tirelessly on this theme at meetings up and down the U.S.A. He also initiated the passage of a Federal Law regulating the safer manufacture and sale of lye solutions.

His professional career with all its successes too numerous for any one man to recall, so greatly honoured was he by every medical fraternity in the world, gave very little inkling of his private life, and it is almost unbelievable that he ever could have had a private life, so much was his time occupied in the fervour of his work. When I knew him I found it difficult to realize that this famous person of nearly 70 years of age was a human being in many ways like other human beings. The remoteness given to high achievement enveloped him, and there was almost nobody then who could claim any degree of intimacy. He was always "the Chief" to everybody, to be approached with great awe and some inward trembling, and he seemed rarely to unbend. Nevertheless, when approached, he was unfailingly courteous and helpful. He had many obvious mannerisms. Like his French forebears he paid no deference to climate and always wore his formal thick black suit, complete with waistcoat, in any day that Philadelphia could produce, and a temperature in the nineties and a humidity of nearly a hundred would make him relax nothing of his dress. In addition, he always wore cotton gloves to avoid touching anything contaminated, whilst a clean towel was always placed in his hand before he took up a telephone. Even his fruit had to be washed in disinfectant before he would eat it. I never knew him take lunch, and even when joining in the farewell luncheon which always ended his famous "Bronchoscopic Courses" he would sit in the seat of honour slowly sipping China tea while all round him were devouring the usual steak. These and numerous other eccentricities of thought and behaviour added to the difficulty of coming close to him. There seemed to be so little in common between so exalted and dedicated a person and the common herd. But as soon as he got to his home in Schwenksville, thirty-odd miles from Philadelphia, he was

completely different. He had purchased an old water-mill on the edge of a weir together with a mile of creek in the middle of some wild old Pennsylvania countryside, or rather countryside which he had allowed to revert to its original wildness. The mill had been disused for years, but to Jackson nothing mechanical was a mystery, and he soon got it going again. He would throw the huge oak gear-levers into position and all the great hickory machinery would begin turning again as it had done in the past. Nothing delighted him more than to demonstrate the great wooden wheels meshing one into the other, noiselessly and efficiently. In earlier days the mill brought in some much-needed income, as well as providing his electricity.

He built himself an armchair with a wide wooden arm in which he would spend hours writing or sketching. Pictorial art was the other side to his life, and he had an aesthetic perception of unusual quality coupled with a very considerable self-taught technical capacity. He drew and painted simple and natural subjects, and those fortunate enough to possess them will know that his drawings and paintings have real artistic merit. At one time he would send Christmas cards to all his friends printed in colour from a painting he had made specially for the occasion, and these were sought after by the *cognoscenti*. All the illustrations in his books were drawn or painted by himself.

In his relations with his family he was never seen to be outwardly emotional, but it was clear that he studied every detail of their comfort and well-being. This applied also to his pupils, although there again it was not easy to achieve any familiar footing with him. Nevertheless one pupil will never forget the messenger boy on the transatlantic liner calling out his name and presenting him with a radioed telegram the length of an ordinary letter greeting him on his journey to the U.S.A., and explaining the arrangements made for his reception. Acts of real humanity and understanding like this, so deeply cognizant of the apprehensions in a young person's mind in going to a strange country and to a new job, clearly showed his feeling for the common touch.

In spite of his intense absorption in his work, his asceticism, and his abstention from all political and personal topics, few men in any generation have aroused so much feeling among their professional contemporaries, voiced by so much overt criticism. It seemed to me, coming on the scene when the dust had settled on these forgotten parochial controversies, that much must have stemmed from a lack of sympathy, that much must have stemmed from a lack of understanding of his idealism. Furthermore, as Jackson became more and more wrapped in his work he may sometimes have seemed to give less than credit to his predecessors and colleagues. I am convinced this was due to absorption rather than to egotism. The differences may also have widened by the peculiar form of design for living affected by, or natural to, Chevalier Jackson. He taught his surgical art to all who came for tuition, and gave them every help he could to found departments similar to his own. To his more personal assistants he was helpfulness and kindness personified.

It is thus the more to be regretted that, in all the mass of Jackson's writings, he found time only for one short autobiographical record, published in 1938. This, however, is titillating in its allusions. British laryngologists would particularly have liked a more expanded account of his visit to the Golden Square Throat Hospital in 1886.

Chevalier Jackson enjoyed the use of all his faculties until very near his death. He had particularly retained the depth and vigour of his intellect, and I sincerely hope that, in his own way, he savoured to the full the unique and legendary place in medicine which time and his long years had brought to him.

The photograph of Dr. Chevalier Jackson was taken when he was 65 and is reproduced by permission of the Macmillan Company, New York, and of Underwood and Underwood.

STANLEY WORTHINGTON, M.D., D.P.H., B.Hy.

Dr. Stanley Worthington, formerly a divisional medical officer of the Ministry of Health, died on July 23 at the home of his son at Nafferton, East Yorkshire. He was 69 years of age.

Stanley Worthington was born at Newcastle upon Tyne on October 7, 1888. He received his medical training at Durham University and Newcastle Royal Infirmary, and graduated M.B., B.S. with honours, in 1910, proceeding to the M.D. in 1923. After resident posts in Newcastle and Glasgow he entered general practice in Newcastle in 1913, obtaining the D.P.H. and the B.Hy. in the following year. Later in 1914 he joined the Royal Naval Medical Service as a temporary surgeon, serving throughout the first world war, mostly in battle-cruisers. He returned to practise in Newcastle after the termination of hostilities, and in 1920 married Dorothy, the daughter of Dr. E. Barker, of Hull. He held various appointments in the Newcastle area—physician to Newcastle Dispensary and Northumberland Chest Hospital and anaesthetist to Newcastle Dental Hospital. He was chairman of the Newcastle upon Tyne Division of the British Medical Association in 1929–30, and took a very active part in the work of the Newcastle Local Medical and Panel Committee.

In 1931 Dr. Worthington left general practice to join the Ministry of Health as regional medical officer, serving first in Sheffield and then in Leeds. In 1948 he became divisional medical officer for the north-east division, with responsibility for an area extending from Berwick on Tweed to as far south as Derbyshire. When he retired from the services of the Ministry in 1956 the Leeds Local Medical Committee entertained him to dinner and made him a presentation as a small measure of its very real appreciation of his many services to the general practitioners of Leeds and his divisional area, and for his generous understanding of the many problems which beset the general practitioner. Although a servant of the Ministry of Health, most general practitioners looked on him as a friend, though he could be quite tough when required. He and his wife were delightful hosts: their hospitality was noted, and he was never happier than when in his own house surrounded by his many friends. Though small in stature, he had a big heart. He faced a very serious illness after his retirement with the courage which those who knew him well had long appreciated. After a severe operation he did not live an invalid life, but, choosing to live rather than exist, took part in most social activities. He maintained a keen clinical interest in medicine up to the time of his retirement, and was a most regular attendee at all the meetings of the Leeds and West Riding Medico-Chirurgical Society. He was devoted to his wife, his son, Dr. Guy Worthington, and his daughter and their families, and to all these the sincere sympathy of his many colleagues is extended. They mourn the loss of a delightful soul.—J. A. L. V. J.

B. HALLEY STEWART, M.D.

Dr. B. Halley Stewart, president of the Sir Halley Stewart Trust, died at Hadley Wood, Middlesex, on July 30. He was 84 years of age.

Bernard Halley Stewart was born at St. Leonards-on-Sea on May 6, 1874, the younger of the twin sons of Sir Halley Stewart, and was educated at University College School, Hastings, and at Bishop's Stortford. An exhibition in science took him to Jesus College, Cambridge, where he obtained second-class honours in the Natural Sciences tripos in 1896. His early ambition was to be a schoolmaster, but on leaving Cambridge he entered his father's business at Rochester, where he remained for several years. Turning to medicine, he studied at Guy's Hospital and graduated B.Chir. in 1904. Obtaining the Cambridge M.B. three years later, he proceeded to the M.D. in 1911. After graduation he held the appointments of assistant house-surgeon at

Guy's Hospital and clinical assistant at the Hospital for Women, Soho. In 1905 he entered general practice at East Bergholt, Suffolk, but left there after three years to settle at Barnet, where he was a member of a partnership until 1929. In that year an accident and an illness caused his premature retirement, much to the regret of his patients, colleagues, and friends. At Barnet he lived in a house opposite the Congregational church, where his grandfather, the Rev. Alexander Stewart, was minister in 1823. In addition to the work of the practice Dr. Stewart was medical officer to the Barnet Union, having the medical care of the inmates of the old workhouse, which later became known as the Wellhouse Hospital, and performed most of the surgery there. He was also surgeon, subsequently consulting surgeon, to the Barnet Victoria Cottage Hospital, and to other local institutions. During the first world war he served as a medical officer at Lady Guernsey's V.A.D. Hospital at St. Omer, and later as an officer in the R.A.M.C., also in France.

From 1937, when he succeeded his father, until his death he was president of the Sir Halley Stewart Trust. Elected a Fellow of the Royal Society of Edinburgh in 1939, he was also a Fellow of King's College, London, and a member of the delegacy of the college. A governor of Guy's Hospital, St. Bartholomew's Hospital, and the Brompton Hospital until the inception of the National Health Service in 1948, he was also a member of the Asthma Research Council. He was chairman of the Barnet Division of the British Medical Association in 1935-6. On his retirement from practice he went to live at Totteridge, moving to Hadley Wood four years ago. Keenly interested in all kinds of sport, as a young man he excelled at Association football, athletics, and swimming, and, subsequently, at tennis. But for an injury to his knee he would probably have represented Cambridge at athletics and swimming. Until quite late in life he retained the magnificent physique he had developed through his devotion to gymnastics as a young man. He was a vice-president of the Hertfordshire lawn tennis association, the Barnet boxing and hockey clubs, and the Hendon Rugby football club. Outstandingly good at chess, he represented Sussex while still at school, playing at the same time for the South versus the North of England. He married Miss Mabel F. Wyatt at Beckenham on April 11, 1905, and so, three years ago, had the happiness of celebrating the fiftieth anniversary of his wedding. He leaves a widow and two sons and one daughter. One of his sons, Dr. H. C. Stewart, has followed him into the medical profession.

H. L. NEIL, M.B., Ch.B.

Dr. H. L. Neil, who was in practice at Horbury, near Wakefield, for many years, died on July 27 at his home at Holt, Norfolk, after a long illness. He was 70 years of age.

Hugh Loudon Neil received his medical education at Glasgow University, graduating M.B., Ch.B. in 1911. During the first world war he served in the R.A.M.C. in France and Mesopotamia. He began general practice in Horbury in 1920, and remained there for 36 years until ill-health caused his retirement in 1956. He was in partnership with his brother, Dr. George Loudon Neil, until the latter's death in 1950.

A. G. writes: Hugh Neil was a most skilful and conscientious doctor who had wide professional interests. He was particularly interested in child welfare and was for many years associated with the clinic in Horbury. He had also been medical officer of health for the town, and was in charge of the local infectious diseases hospital until its closure in 1948. Like most practitioners of the old school, he was a highly skilled obstetrician. During the second world war he played a prominent part in organizing the first-aid services in the area. He was a kindly, modest man, devoted to his work and his patients, and will be greatly missed. His final illness was a very long and painful one,

which he bore with great courage. In recent years, although he could hardly walk, and every step he took caused him severe pain, he continued to visit his patients until this was no longer possible. He leaves a widow, three sons, and a daughter.

F. E. JOHNSON, M.R.C.S., L.R.C.P.

Dr. F. E. Johnson died at his home at Stanmore, Middlesex, on August 10 after a short illness. He was 67 years of age.

Frank Edwin Johnson was a native of Devonport, where he was born on February 2, 1891. He qualified M.R.C.S., L.R.C.P. from the London Hospital in 1913. Immediately the first world war broke out he joined the R.A.M.C., and while serving as a regimental medical officer in France he was exposed to one of the first gas attacks, before masks were available. As a result his lungs were permanently damaged. After the war he transferred to the R.A.F. and was one of the few medical officers to gain his wings. On his retirement from the R.A.F. in 1946 he settled in practice at Stanmore, where he soon became appreciated by his patients and respected by his colleagues. His unfailing kindness, good humour, and strict sense of duty were outstanding, and his passing is a sad loss to those he served so faithfully and to a wide circle of friends. He leaves a widow and four children. His elder brother, Dr. J. Pratt-Johnson, is well known as a bacteriologist in Johannesburg. —McN. L.

H. J. BEDDOW, M.R.C.S., L.R.C.P.

Dr. H. J. Beddow, honorary consulting anaesthetist to the Hospital of St. Cross, Rugby, died on August 11 at the home of his son at Nymet Rowland, Lapford, Devon, where he had been living in retirement. He was in his 80th year.

Harold Josiah Beddow was born at Ealing on August 20, 1878. From Dulwich College he entered Christ's College, Cambridge, to read medicine, receiving his clinical training at St. Bartholomew's Hospital. Qualifying M.R.C.S., L.R.C.P. in 1907, he then held the appointment of house-physician at Bedford County Hospital before entering general practice at Rugby in 1909. His experience in the first world war, in which he served as a captain in the R.A.M.C. at the 72nd General Hospital in France, aroused an interest in anaesthesia, and on his return to civilian life he was appointed anaesthetist to the Hospital of St. Cross at Rugby. With operations at the hospital becoming more frequent, he gave up more and more of his time to the work, in which his imperturbable nature stood him in good stead. Always spruce in appearance and always cheerful, he will be remembered by his many patients for his unfailing kindness, and by his colleagues at the hospital and in general practice for his willingness to act as anaesthetist at any time of the day or night, and for the quietly efficient way he did this work. A member of the British Medical Association for nearly 50 years, he was a founder member of the Rugby Division in 1927 and chairman from 1934 to 1936. He remained an active member of the Division on the executive committee until just before he retired in 1946. He was also a member of the Warwickshire Local Medical Committee for many years. A typical family physician, he loved to hear from his old patients, whom he always regarded as his friends. He leaves a widow and one son, the Rev. A. J. C. Beddow.

J. B. BISHOP, T.D., B.M., B.Ch.

The obituary of Dr. J. B. Bishop was printed in the *Journal* of August 16 (p. 453).

Dr. PATRICK G. McGRATH writes: Brock Bishop had a tremendous zest for the full life. His interests were wide, and to each one of them, social, professional, and purely

recreational, he gave a full measure of his abundant energy. I saw this mainly in his medical work, where his conscientious attention to every facet of the life of his patients not only paid handsome clinical dividends but earned him the respect and deep affection of patients and colleagues. His devotion to duty did not result in a dreary rigidity, but was clothed in a vivid, flexible human approach; the patients' own attitude and susceptibilities would extract from Brock the formal courtesy of which he was a master, or, through the whole gamut, to a friendly raciness of language which on occasion enlivened his reports as well. The memorial which he would appreciate most is the affectionate smile which comes to every face in Broadmoor at the mention of his name.

FELLOW TERRITORIAL writes: It was with sad surprise that I read of the death of John Brock Bishop, followed by a feeling of pride and gratitude at having had the privilege of his friendship. He had been medical officer to the 51st Heavy Anti-Aircraft Regiment, R.A., T.A. (London), and it was on his promotion to senior medical officer of his brigade in 1939 that we first met. His constant good humour and ready but subtle wit enabled him to fill this post with efficiency and popularity. I later met him during the invasion of Sicily, when he held another staff appointment, and again later during the campaign in Italy, when he held a similar post. At this period we spent together a never-to-be-forgotten leave in Rome, when he was the jolliest of companions. I later called on him at Broadmoor, where he was obviously happy and had found his niche where he could help his less fortunate fellows. "Brock" was a man who walked humbly but nevertheless held firm convictions quietly. He was a gentle man by whose passing the world is poorer.

Vital Statistics

Week Ending August 16

Despite the unseasonable summer weather, infectious diseases in England and Wales remained generally at a low level in the week ending August 16. Increases in the number of notifications were recorded for whooping-cough 106, acute poliomyelitis 13, from 73 to 86, acute pneumonia 33, from 150 to 183, and food-poisoning 116, from 171 to 287. Notifications of the following diseases from fell: scarlet fever 37, from 410 to 373, measles 476, from 5,578 to 5,102, and dysentery 29, from 367 to 338. Cases of paratyphoid fever numbered 5 and typhoid 4, for each of the same as the previous week.

The 86 cases of acute poliomyelitis comprised 57 paralytic and 29 non-paralytic; these were 6 and 7 respectively more than in the previous week. The main centres of infection continued to be Yorkshire West Riding 26 (Leeds 7, Morley M.B. 2), and Lancashire 13 (Manchester C.B. 7, Stretford M.B. 2). In Devon 7 cases were notified, all from Plymouth C.B.

An outbreak of 70 cases of food-poisoning was reported from Hampshire (Basingstoke R.D.).

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during 1958 are shown thus ———, the figures for the years 1949-57 are shown thus ———. Except for the curves showing notifications in 1958, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending August 9 (No. 32) and corresponding week 1957.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the whole of England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

† Includes primary and influenza pneumonia.
‡ Includes puerperal pyrexia.

Medical News

Smoking and Lung Cancer Propaganda.—The Minister of Health has circularized local authorities asking them to report on what steps they have taken to bring the risks of smoking to the notice of the public. The inquiry follows a circular in June last year in which the Minister asked that information on the dangers of smoking and its association with lung cancer should be disseminated. Local authorities are now asked to say whether they have accepted the need for a propaganda programme. If so, they are asked to report what publicity methods and material have been used, and whether they have been concentrated on special groups and if any of them have been especially effective. An assessment of the public reaction is also asked for.

Medical Art Exhibition at Edinburgh.—During the Joint Annual Meeting of the British and Canadian Medical Associations at Edinburgh from July 20 to 24, 1959, there is to be an exhibition of paintings by members of the two Associations. By courtesy of the governors and principal of the Edinburgh College of Art this exhibition will be held in the Andrew Grant Gallery of the College throughout the Meeting. Accepted work will be limited to approximately 150 exhibits, and should be either oils or water-colour paintings. A prize has been offered for the most outstanding exhibit. Members who wish to exhibit examples of their work on this occasion are invited, in the first instance, to communicate either with Professor B. G. MAEGRAITH, School of Tropical Medicine, University of Liverpool, Pembroke Place, Liverpool, 3; Dr. A. M. RACKOW, Cleve Cottage, Hawk's Hill, Leatherhead, Surrey; or Professor D. E. C. MEKIE, Royal College of Surgeons, 18, Nicolson Street, Edinburgh, 8.

The Lambeth Conference and Family Planning.—The report of the Lambeth Conference of bishops, published earlier this week by the S.P.C.K., includes a section on "The Family in Contemporary Society." Of the three main purposes of marriage defined by the Conference, the procreation of children is mentioned first. The earlier in marriage children are born the better both for them and for their parents. But, the report states, "family planning, in such ways as are mutually acceptable to husband and wife in Christian conscience, and secure from the corruptions of sensuality and selfishness, is a right and important factor in Christian family life. . . . Scientific studies can rightly help, and do, in assessing the effects and usefulness of any particular means, and Christians have every right to use the gifts of science for proper ends." The Conference welcomed the growth of marriage guidance councils, which made an important contribution to the community and deserved Government support. Clergy should be encouraged to offer themselves for training as counsellors. Referring to countries where the increase of population imperils the survival of young and old, the report urges that it is the duty of the better-developed nations to help them to become self-supporting. "Abortion and infanticide are to be condemned, but methods of control (of population), medically endorsed and morally acceptable, may help people of their lands so to plan family life that children may be born without a likelihood of starvation." Any government policy of compulsory sterilization as a means of population control is unacceptable to the Christian conscience. Where conception is prevented by physical or emotional abnormality, the Christian can rightly accept the help of responsible physicians. But, the report continues, "artificial insemination by anyone other than the husband raises problems of such gravity that the committee cannot see any possibility of its acceptance by Christian people."

Overcrowded Prisons.—The "outstanding feature" of the prisons in 1957 was "the steady rise in the inmate population with the consequent return of accommodation

problems." The Report of the Commissioners of Prisons for the Year 1957 (H.M.S.O., 9s. 6d.) states this and adds: "Nevertheless the general health of the inmates was well maintained." The daily percentage receiving medical treatment in and out of hospital was 15.5. This relates to an average prison population of 22,602. The percentages in previous years were: 1956, 15.6; 1955, 14.6; 1954, 13.8; and 1953, 13.9. Large numbers of prisoners contracted Asian influenza, so that, apart from this disease, ill-health seems to have been less prevalent than in the previous year. Deaths numbered 60, of which 47 were from natural causes. Of the remaining 13, 8 were due to suicide, 2 to judicial execution, 1 to a fight with another prisoner, 1 to jumping from a moving car, and 1 to asphyxia in an epileptic fit. Of the 47 deaths from natural causes, 12 resulted from malignant disease. In an attempt to assess the results of psychotherapy, some figures for the Wormwood Scrubs psychiatric unit are given. They suggest that sex cases responded better than non-sex cases (success rates 48% and 37%), and that group psychotherapy was more beneficial than individual psychotherapy (success rates 53% and 42%). It is recognized that the selection of patients may influence the validity of these figures.

Society of Apothecaries.—At a meeting of the Court of Assistants on August 19, the following were elected officers of the society: *Master*, Dr. W. S. C. COPEMAN; *Senior Warden*, Dr. RICHARD R. TRAIL; *Junior Warden*, Dr. CHARLES WHITE.

Carbon Dioxide Danger.—The wet harvest has increased the danger of carbon dioxide asphyxiation among farm workers. The Ministry of Agriculture has reminded farmers that accumulation of wet grain generates the gas in a matter of hours. This can happen in any place where grain is stored, and as the gas is heavier than air it will collect in the pits or ducts of a grain-handling plant.

Winning Flautist.—Dr. W. K. VERNON BERNFELD won the solo flute competition, for the second year in succession, at the eisteddfod held recently at Ebbw Vale.

Lord Webb-Johnson.—A cheque for £20 has been sent to the Royal Medical Benevolent Fund as a result of a collection taken in memory of Lord Webb-Johnson at his old school—the High School, Newcastle-under-Lyme.

COMING EVENTS

Occupational Health.—A short intensive course for general practitioners in occupational health will be held at the London School of Hygiene and Tropical Medicine from September 22 to 26, inclusive. Fees and allowances are provided for National Health Service practitioners on certain conditions. Other practitioners may attend on payment of a fee of 5 guineas. Numbers admitted to the course are strictly limited, and only a few vacancies remain, but applications and requests for further information may still be sent to the Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1.

Space Medicine.—The British Interplanetary Society will hold a symposium on this subject at B.M.A. House, Tavistock Square, London, W.C.1, on October 16-17. The symposium is being organized with the co-operation of the R.A.F. Institute of Aviation Medicine. Full details from the secretary of the Society at 12, Bessborough Gardens, London, S.W.1.

Radioactive Risks.—The Scottish Group of the Nutrition Society is holding a symposium on "Nutritional Hazards Caused by Radioactive Contamination of Foods" in Edinburgh on September 27. Those interested who are not already members of the Society are invited to write for further particulars to Dr. J. DAVIDSON, Rowett Research Institute, Bucksburn, Aberdeenshire.

Chartered Society of Physiotherapy.—Conference on "Work Study—Its Application to the Hospital Service," October 17 and 18, at the Meyerstein Lecture Theatre, Westminster Medical School. Details from the secretary, Tavistock House (South), Tavistock Square, London, W.C.1.

NEW ISSUES

SPECIALIST JOURNALS AND ABSTRACTS

The journals listed below are obtainable from the publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Archives of Disease in Childhood.—Issued six times a year (£4 4s. annually). The new issue, Vol. 33, No. 170, includes:

PAEDIATRICS IN WESTERN NIGERIA. Malcolm Macgregor.
PHLYCTENULAR CONJUNCTIVITIS IN AFRICAN CHILDREN. Harry Stein and Ida Freiman.
HORMONE EXCRETION IN PRECOCIOUS PUBERTY IN GIRLS. R. D. Bulbrook, F. C. Greenwood, and A. H. Snaith.
URINARY EXCRETION OF 17-KETOSTEROIDS IN CHILDREN. Margaret Prout and A. H. Snaith.
THE URINARY EXCRETION OF 17-HYDROXYSTEROIDS IN CHILDREN. R. Gardner and A. Snaith.
THE PROGNOSIS IN JUVENILE OBESITY. A. G. Mullins.
DIABETES INSIPIDUS FOLLOWING TUBERCULOUS MENINGITIS. John Lorber.
DIABETES MELLITUS IN A CHILD SHOWING FEATURES OF REFSUM'S SYNDROME. J. B. Heycock and J. Wilson.
THE POST-NATAL WEIGHT LOSS OF BABIES BORN TO DIABETIC AND NON-DIABETIC WOMEN. James W. Farquhar and Stanley A. Sklaroff.
JAUNDICE AND INFANTILE DIARRHOEA. R. G. F. Parker.
CONGENITAL SPHEROCYTOSIS IN INFANCY. David Butman.
CONGENITAL HEART DISEASE IN ONE OF IDENTICAL TWINS. H. Everley Jones.
THE ELECTROCARDIOGRAPHIC RECOGNITION OF VENTRICULAR HYPERTROPHY IN CONGENITAL CARDIOVASCULAR DISEASE DURING THE FIRST YEAR OF LIFE. J. S. Oldham.
THE DIFFERENTIAL DIAGNOSIS OF RHEUMATIC FEVER. K. A. Hallidie-Smith and E. G. L. Bywaters.
A SMALL OUTBREAK OF NEONATAL MENINGITIS IN A MATERNITY UNIT. Eric McKay and John Smith.
NEONATAL PERFORATION OF THE COLON. Leonard Haas.
BILATERAL PULMONARY AGENESIS. Albert E. Claireaux and H. P. Ferreira.
ATRESIA OF THE OESOPHAGUS WITH COMMON TRACHEO-OESOPHAGEAL TUBE. R. G. Welch and O. A. N. Husain.
PSYCHOGENIC MEGACOLON IN CHILDREN: THE IMPLICATIONS OF BOWEL NEGATIVITY. Philip Pinkerton.
BRITISH PAEDIATRIC ASSOCIATION: PROCEEDINGS OF THE TWENTY-NINTH ANNUAL GENERAL MEETING.

British Journal of Ophthalmology.—Issued monthly (£6 annually). The new issue, Vol. 42, No. 8, includes:

VISUAL DISTORTION IN AMBLYOPIA. M. Pugh.
ATTEMPTED ISOLATION OF THE VIRUS OF TRACHOMA. C. H. Smith, M. J. Gilkes, and J. Sowa.
STAINING OF INCLUSION BODIES OF TRACHOMA AND INCLUSION CONJUNCTIVITIS. M. J. Gilkes, C. H. Smith, and J. Sowa.
TRACHOMA INCLUSIONS AND PENICILLIN. M. J. Gilkes, C. H. Smith, and J. Sowa.
A NOTE ON THE MODE OF ACTION OF TARSORRHAPHY IN NEUROPARALYTIC KERATITIS. P. Sivasubramanian.
CORNEAL "FLAP" INCISION FOR CATARACT OPERATION. A. Gormaz B.
EXPERIMENTAL ELECTROCHEMICAL REMOVAL OF COPPER SPLINTERS FROM THE ISOLATED VITREOUS. T. Krawicz and K. Zagorski.
OCULAR MANIFESTATIONS IN IDIOPATHIC HYPERLIPAEEMIA AND XANTHOMATOSIS. P. K. Thomas and E. B. Smith.

Abstracts of World Medicine.—Issued in the first week of each month, this journal contains abstracts of important papers selected from the current medical literature of the world. Annual subscription £4 4s.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Friday, September 5

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. J. G. Scadding: clinical demonstration.

Sunday, September 7

UNIVERSITY COLLEGE HOSPITAL.—10.15 a.m., lecture-demonstration for general practitioners. Clinical demonstration by Mr. G. L. Buntin: Some Aspects of Cases Suitable for Paediatric Surgery. Meet in front hall of main hospital building.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Hinton.—On July 12, 1958, to Rosalind (formerly Elliott), M.B., B.S., D.Obst., R.C.O.G., wife of Lieutenant-Commander J. D. O. Hinton, R.N., of Overbank, Barclays Bank, Littlehampton, a daughter.

DIAMOND WEDDING

Rawson—Hammond.—On August 24, 1898, William Foster Rawson, F.R.C.S.Ed., F.R.C.O.G., to Helen M. Hammond. Present address: "Clevedon," Park Drive, Bradford, 9.

DEATHS

Adam.—On August 11, 1958, in hospital, Robert Stuart Adam, M.B., Ch.B., of 236, Great Clowes Street, Broughton, Salford, Lancs.
Attenborough.—On August 13, 1958, in St. John and St. Elizabeth Hospital, Grove End Road, London, N.W., Keith Edward Attenborough, M.R.C.S., L.R.C.P., of 1, Mortimer Court, Abbey Road, London, N.W.
Beddow.—On August 11, 1958, at The Rectory, Nymet Rowland, Lanford, Devon, Harold Josiah Beddow, M.R.C.S., L.R.C.P., late of Rusby, Warwick, aged 79.
Golden.—On August 11, 1958, Stanley John Golden, M.B., B.S., F.R.C.S., of 236, Great Clowes Street, Broughton, Salford, Lancs.
Ross.—On August 24, 1958, Henry Ross, C.I.E., O.B.E., F.R.C.S.I., Lieutenant-Colonel, I.M.S. (retired), of The Cottage, Hovingham, York, aged 81.

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Standard of Hygiene and Poliomyelitis

Q.—The trend of medical opinion is that the spread of poliomyelitis is probably by faecal contamination. Yet the W.H.O. expert committee's second report¹ associates poliomyelitis epidemics with a general improvement in hygiene and sanitation, and regards a fall in infant mortality below 75 per 1,000 live births as a warning sign. How may these apparently contradictory views be reconciled?

A.—An inverse correlation between the height of the infant mortality rate and the intensity of polio epidemics appears to be true for many countries. It can be explained if the distinction between infection of the alimentary tract with polio virus and paralytic disease is borne in mind. Under conditions of bad sanitation faecal infection probably occurs at a very early age, when maternal antibodies are still present and able to prevent spread of virus from the gut to the C.N.S. Further episodes of oral infection create a solid active immunity, and widespread prevalence of the virus exists in the apparent absence of poliomyelitis as a disease. In highly civilized communities good sanitation prevents faecal infection, so that the first contact with virus occurs in infants, children, or even adults who possess no active immunity and no antibodies to protect the C.N.S. A sparing of infection with polio virus in infants by the hygiene of food and water therefore renders the community more liable to paralytic attacks. Virus is less prevalent but the disease is epidemic.

REFERENCE

¹ Expert Committee on Poliomyelitis: Second Report, *Wld Hlth Org. techn. Rep. Ser.*, 1958, No. 145.

Medical Blood Donors

Q.—Are there good reasons why nurses and doctors who are healthy and between the ages of 18 and 65 should not enrol as blood donors?

A.—Blood donation may produce acute or chronic effects. The acute effects are those, such as mild faintness and giddiness, associated with sudden depletion of blood volume; these effects last for only a few hours and are unlikely to be troublesome unless the donor has to engage in some strenuous task during this period. The chronic effects of blood donation are mainly due to iron depletion, and may be adequately counteracted by taking iron, and are in any case unlikely to be important if the intervals between donations are as long as six months, as is the case in the United Kingdom.

It may be argued that some doctors and nurses lead a particularly strenuous life, and that they should be spared any additional physical burden. Probably they should be discouraged from acting as blood donors, although they should surely be allowed to give blood occasionally (perhaps once a year) if they express a strong wish to do so.

Mortality from Whooping-cough

Q.—What are the causes of mortality from whooping-cough in the very young, and what measures may be taken to prevent or treat these?

A.—In the first year of life, especially in the first three months, babies with whooping-cough are especially liable to asphyxial attacks. Convulsions are also common: these may accompany the asphyxial attacks or they may occur independently and are then presumably caused by toxic damage to the brain. Bronchopneumonia is common, often with pulmonary collapse. Gastro-enteritis is especially dangerous.

Babies with severe whooping-cough need constant observation. If there is any tendency to asphyxial attacks they

should be nursed in oxygen tents or boxes: this, along with sedatives, may lessen the asphyxial attacks and associated convulsions. No treatment seems to be effective for the second type of convulsions: when they are severe and repeated, the child usually lapses into coma. Lumbar puncture is certainly useless: sedatives and anaesthetics may produce some effect and cortisone has been tried, but without convincing results. Bronchopneumonia usually responds to the appropriate antibiotic and pulmonary collapse to postural drainage. Gastro-enteritis may respond to an antibiotic according to the organism responsible, but the condition should be prevented by rigid isolation. Cross-infection is in fact one of the main hazards for the infant with whooping-cough. First-class nursing, with especial attention to maintaining nutrition, is the most important item in the prevention of bronchopneumonia and gastro-enteritis. Once an attack has developed vaccines are, of course, useless.

NOTES AND COMMENTS

"Wind."—Dr. ISAAC EBAN (London, W.1) writes: Your expert's reply ("Notes and Comments," August 2, p. 340) deserves praise in being both correct and to the point. Most of the gas in the bowel, which can be a source of trouble to the diagnostic radiologist, is not intrinsic but extrinsic in origin. In other words, it comes less from the products of digestion than from air which is swallowed. Also, the more apprehensive the patient the more will be the amount of air swallowed. Therefore the sensible thing to do if one wants to keep the bowel gas at a minimum is to "tranquillize" the patient at the beginning of the investigation (this can be done by giving two tranquillizing tablets, preferably crushed) and also to prevent air-swallowing by making the patient bite on a cork during the whole investigation, for this makes swallowing practically impossible. Before doing the latter, it is, of course, advisable to secure the patient's co-operation by explaining to him the why and wherefore of the proceeding. The good results thus obtained can be made even better by the use, on the evening previous to the x-ray investigation, of two "contact-action" tablets, and the use, on the morning of the day of the investigation, of a suppository which acts by "contact" with the rectal mucosa. The gratifying absence or almost complete absence of gas in the bowel resulting from the use of the above technique is especially helpful in intravenous pyelography cases.

Correction.—The report of the discussion on the surgical treatment of congenital heart disease at the Section of Cardiology (July 26, p. 233) omitted a point made by the speakers to the effect that atrial septal defects should be repaired at present in special centres, where the operative mortality was low, and that the appearance of cardiac enlargement or of symptoms was an urgent indication for surgery. Dr. E. M. M. BESTERMAN emphasized that cardiac enlargement preceded symptoms in atrial septal defects and that this was an indication for surgery, regardless of a patient's youth. He mentioned that in a series of 100 cases operated on at the Middlesex Hospital there had been only three deaths.

Collected Articles from the "British Medical Journal"

THE EDUCATION OF THE SCIENTIST*

BY

Sir ERIC JAMES

High Master of Manchester Grammar School

Although it is a pleasure and an honour to be asked to speak to doctors on the education of the scientist, it is a pleasure mingled with a good deal of misgiving. First there is the perennial problem, that even the great Wilfred Trotter left unsolved, of whether medicine itself is an art or a science. Secondly, there is the fact that a subject on which everyone is apparently an expert, and on which everyone feels entitled to express an opinion based on his own schooldays thirty years before.

Nevertheless, I am encouraged by the importance of the subject itself. There is no field of education to which it is more worth devoting thought than that of the place of science. This is true because the actual proportion of our ablest pupils who specialize in science has increased considerably over the past few years, and is undoubtedly will go on increasing still further. It is also very important to take account of the fact that as a greater proportion of our national ability is devoted to science it will be increasingly necessary to recruit our administrators and executives from those trained in science rather than the arts, as in the past, and their education thus assumes an ever greater significance.

Rapid Growth of Knowledge

In discussing the education of the scientist it is necessary to remind ourselves from time to time what a comparatively recent problem this presents. It is only a century since the then headmaster of Winchester told the Clarendon Commission on the public schools how impossible it was that scientific subjects should ever become a regular part of the time-table. Since then, and particularly in the last twenty years, we have seen an astonishingly rapid growth, so rapid indeed that nearly two-thirds of our much-expanded sixth forms are studying science in some aspect. The rapidity of this change has considerable bearing on the criticisms that are often made of our scientific education. In so far as they relate, as they so often do, to the critics' own schooldays, they are concerned with a state of affairs that has passed for ever. This great change in the position of science has come about as a result of profound social and economic changes. But more than that, it has come as a result of the pressure of new knowledge.

At no time in man's history has there been a more spectacular growth of knowledge than in the natural sciences in the past half-century, and it is well that we

*The substance of a lecture delivered to the Manchester Medical Society on May 7, 1958.

should remind ourselves of the difficulties this has created for the educator. Compared with the task of, say, Arnold a century ago, our problems in devising a curriculum which shall be an adequate preparation for life are far more difficult. Then a curriculum whose domination by the classics was mitigated only by a little mathematics was sufficient. Now we have had to add a multiplicity of other subjects; we have to take account of the emotional and physical education of our pupils, and we have to prepare our boys and girls ultimately to contribute to the development of knowledge itself. At its deepest level the task of education may be the same, to produce rational and civilized human beings. But the meaning of civilization has broadened, and superimposed on that task is the obligation to produce some individuals who will be able to reach the frontiers of knowledge, even though with every year that passes, those frontiers are becoming more remote.

Real Progress

Having sketched that background, let us turn to a more detailed examination of our subject. First, let us consider the education of the scientist in science. Here, I believe, we can claim real progress. The efforts of science teachers themselves, reinforced by an able and enlightened inspectorate, have encouraged real advances in the quality and quantity of science teaching. We are rapidly moving towards the position in which some science is part of the education of all suitable children from the age of 11. A weakness that is at present too common is that children often have to decide too early whether they wish to specialize in science; but even here we are making progress, and moving towards a situation in which no irrevocable decisions have to be made until 15 or 16. After that age, in the sixth form, it is, as is well known, the custom in English schools to specialize fairly intensively. No aspect of education is more freely criticized than sixth-form specialization; no educational topic is discussed more misguidedly. In fact, a reasonable degree of specialization may be defended on grounds both of educational value and of expediency.

It is good for intelligent boys and girls to devote the major part of their energies to their chosen subjects firstly, because they like doing so. It is a frustrating waste of the energy of youth to make a clever boy learn something merely because it is not what he wants to learn. And even at the age of 17 there is virtue for the abler pupil in getting to grips with quite difficult ideas in his chosen subject. But, apart from these more

5096

recognized by the Ministry, and there are still many good courses held each year which have not been recognized.

Difficulties in Postgraduate Study

The College of General Practitioners believes that, except in special circumstances, a family doctor should attend at least twenty hours of organized postgraduate study each year. The optimum amount of formal study will vary for each individual, and will depend on many factors, such as the time at his disposal and how great are his opportunities for self-education. It will be likely to fall between the minimum figure set by the College and the maximum that the Ministry is prepared to subsidize. In stressing the importance of attending organized courses we must remember the danger of a practitioner becoming so obsessed by attending courses that his own practice will suffer. The Ministry has been wise to set a maximum subsidy for this type of postgraduate study.

In the questionnaire members of the College were asked to state what they considered to be the main obstacles to postgraduate work. Their replies are listed as follows:

1. Lack of time	75%	1,224
2. Deputizing difficulties	38%	613
3. Distance from courses	32.5%	525
4. Lack of ancillary help	12%	190
5. Lack of practice in studying	8%	130
6. Courses too elementary	5%	81
7. Courses too highbrow	5%	80
8. Family or social commitments	3.5%	58
9. Financial difficulties	2%	29

These answers are interesting enough to be worthy of further comment.

Lack of time and deputizing difficulties are by far the commonest problems mentioned, and it would be valuable to know why this is so. Attending courses for one or two weeks necessitates either the employment of a locum tenent or a partner taking over the work in the practice. While the Ministry will pay for a locum for a single-handed practitioner, it will not do so for a man in partnership. Consequently the doctor in partnership must rely either on the good will of his partners for leave of absence from the practice, or on the good will of his family to let him use part of his holiday for attending a course. There are two simple solutions to this problem: firstly, the inclusion in every partnership and assistantship agreement of a clause allowing for study leave; and, secondly, for the Ministry to pay for a locum when a doctor in partnership attends a course, as is already done in Scotland.

For meetings of clinical societies, extended courses of half a day, a week, or for week-ends, the problem is different. A full visiting-list may make even a few hours' absence from the practice impossible; a single-handed doctor may have difficulty in finding a "stand-in," and the distance from the lecture or meeting may be too great. Encouraging developments for overcoming these difficulties are the increasing number of evening and half-day rota systems that are being set up, and the tendency for general practitioners in areas distant from teaching centres to establish small discussion groups and clinical societies of their own. Experiments in recorded lectures, described elsewhere in this issue by Drs. John and Valerie Graves, should be of great assistance to isolated doctors and to small groups of doctors holding meetings without a guest speaker.

It is disturbing to note in the answers to the questionnaire⁴ that no fewer than 130 doctors confess to lack of practice in studying. Whether this is due to disillusionment and dislike of the work in general practice or to lack of opportunity, it is a challenge to us all to see that general practice is kept interesting and vital, and that entrants to this branch of the profession are provided with stimulating opportunities for study from the beginning of their careers.

The fact that equal numbers of practitioners say that courses are "too highbrow" and "too lowbrow" shows the need for variety and that some indication of the type of course—for example, revision or recent advances—should be made when the course is advertised.

Organization of Courses

Comments in the questionnaire on courses that general practitioners had attended were usually favourable, but some adverse comments were made about either their administration or their content. The importance of good administration cannot be overstressed. Matters such as lectures starting and ending at the advertised time, allowing adequate time for discussion, and the avoidance of long periods when the doctors on the course are kicking their heels and waiting for the next lecture, must be carefully considered. Discussion following a good lecture is often the most valuable part of it, for this is the time when the general practitioner can mention the problems that have arisen in his own practice—points that may not have been considered in the formal lecture, but which may be clarified in the discussion period by the lecturer or by another general practitioner present.

When choosing the programme for a course the organizers should relate their lectures and demonstrations to a general practitioner's day-to-day work, remembering that 90% of this is concerned with the commoner diseases.

A family doctor who attends a general refresher course will hope to review in detail the commoner conditions and also hear in outline of important developments in the treatment of rarer diseases, and something of the work in the more highly specialized branches of medicine. By careful rearrangement of the programmes from year to year it should be possible to cover the whole of medicine over a period of five or six years. When highly specialized subjects are being discussed it is the overall picture rather than detail that interests the general practitioner. Conversely, when diseases which he usually treats himself are being discussed he will want to know minute details of technique. Many subjects are best considered by a group of lecturers—physician, surgeon, pathologist, and radiologist—each of whom can give his point of view. Those who arrange courses are often well advised to invite a general practitioner of experience to help them in planning the course and in opening or closing discussions. He can explain the general practitioner's viewpoint and ensure that subjects are approached from an angle which will interest his colleagues. Perhaps this helping and advising of the organizers of courses is one of the most important contributions that postgraduate education committees of faculty boards can make to organized postgraduate education for the general practitioner.

Many family doctors prefer to attend a course devoted to one particular branch of medicine, either because they are especially interested in the subject or because they feel that their knowledge of it is weak. Courses of two days or a week are already held in subjects such as obstetrics, psychological medicine, anaesthetics, dermatology, paediatrics, chest diseases, and cardiology. The principles that apply to the organization of general refresher courses apply also to these. The organizers must remember that they are teaching family doctors and not young consultants, and the lecturers should concentrate on broad principles rather than detail.

However many formal courses are arranged, there will always be a number of family doctors who wish to make a detailed study of one or two particular conditions, and for whom there is no appropriate course. The College of General Practitioners is fortunate in being able to award several grants each year to these general practitioners so that they may arrange for themselves suitable courses of study in hospitals and clinics.

Summary

If general practice in this country is to maintain its traditional high standard when medical science and thought are expanding so rapidly, it is essential that the family doctor should be given many opportunities to keep up to date. Though much has been accomplished already, there is still a great deal to be done before

young doctors are adequately trained for general practice, and established practitioners can obtain all the continuing education they require.

It has not been possible in this article to do more than mention briefly some of the main problems and offer a few suggestions to solve them. The views expressed are my own, but I am grateful for the help and encouragement of many members of the College of General Practitioners throughout the country.

KEEPING INFORMED BY TAPE AND DISK

BY

JOHN C. GRAVES, M.R.C.S., L.R.C.P.

AND

VALERIE GRAVES, M.B., B.S.

Medical Recording Service, College of General Practitioners

The idea of being kept informed by tape and disk arose when we were engaged in the analysis of some of the replies to the questionnaire sent out to members of the College of General Practitioners by the College's Postgraduate Education Committee. We were struck by the number of general practitioners who found difficulty in attending courses because of lack of time, deputizing difficulties, and so on. Many said that "few meetings are held in this area now, as it is not worth getting a speaker to come for just a few people." Why not, then, take the meeting to the general practitioner? We decided to make a trial of recorded talks, which, we thought, would not only bring good speakers to those who would not otherwise hear them but also provide an incentive to hold small meetings, with discussion, often as valuable as the lecture itself.

Argument

It may be said that as reading is quicker there is little point in going to all the trouble of recording talks, but the following points should be considered.

Advantages of Auditory over Visual Education.—The spoken word has more power to command and hold attention, and no skill in printing can reproduce the expression, timing, and emphasis by which a speaker brings home his points—let the reader contrast the speeches of Sir Winston Churchill with their printed replicas—but the speaker must be good. There is no better soporific than a bad lecturer. That this is not just a biased impression is suggested by the observations of Joyce and Weatherall (1957), who found, in comparing different methods of education, that auditory methods were best—even the old-fashioned formal lecture, which was only just beaten by discussion groups, which, of course, use far more time and discussion staff. Diagrams, formulae, and pictures can be understood more quickly and easily if the eye is free to concentrate on them while the ear listens to the exposition.

Dangers of Unsupervised and Unplanned Reading.—Joyce and Weatherall found this method of teaching "consistently least effective" for undergraduates, and for postgraduates the danger becomes greater as the time since

qualification increases. The newer the method of treatment, the more strange it will appear, and the greater the chance of articles on it being ignored in haphazard reading.

False Confidence in Reading.—Many doctors suffer from two delusions: (1) that they always read the journals that they buy; and (2) that they, having read a journal, have not missed anything in it. It is a salutary experience to test oneself on these two points. Gaps in knowledge are most readily brought to light by free discussion between friends and equals.

Geographical and Academic Isolation of the General Practitioner.—It is easy to understand that the general practitioner can be cut off by lack of time or by distance from courses; but academic isolation, though less tangible, is no less real. It includes lack of practice in studying and in arranging thoughts and decisions in an academic way. Working alone, the general practitioner may lose the ability for mental gymnastics, so that the rapid cut and thrust of argument at ward rounds may leave him feeling discouraged and inadequate. We hope that the issue of recordings will encourage him to seek out his neighbours to discuss what they have heard, to read in a more selective way, and perhaps to go on ward rounds with a firmer tread. The ideal recording would not supplant formal postgraduate teaching, but would point the way to a fuller use of it.

Novelty of Education by this Means.—The reaction of the average doctor to paper by post is now almost nil, as any organizer of activities knows to his cost, but it is still difficult to resist the appeal of a recording, which cannot be glanced through, and which requires the setting aside of a proper period for its hearing. (Listening while shaving or driving cannot be too strongly condemned.) But the value of this novelty will be irretrievably lost if it is spoiled by the anticlimax of poor material.

Tape-Recording Already used in Education.—In other fields much use has already been made of this valuable tool. Schools use it for many subjects, not only languages, and it is of great value for blind, deaf, or other handicapped children: the prospect is enormous and still largely experimental. Many authorities are building up libraries of educational recordings. In medicine, many subjects, such as cardiology and psychiatry, are particularly suitable, and undergraduate teaching makes some use of recordings. In the United States of America many varieties of recorded education are available, of which we will mention only the Audio-Digest Foundation, which distributes weekly abstracts of literature on tape to medical subscribers, and the Seminar Kits made by the University of Utah College of Medicine, which are lectures on gramophone disks, with illustrations. Some medical societies overseas which have widely scattered members already make recordings of their meetings for members unable to attend.

The Experiment

We proposed to send out, not abstracts or recordings of previous occasions, but talks specially made for the microphone and for our particular audience. The response to only the first two recordings is described. After those, although the experiment continued and merged imperceptibly into the present Medical Recording Service of the College, the scheme was much modified and the "audience" became much larger.

The Listeners.—These were selected by picking out from the replies to the questionnaire 50 of those College members who had said, for one reason or another, that they had been unable to get to courses. They were by no means a random sample or representative of the College as a whole, but they all wanted to keep up to date. Twenty-seven agreed to take part in the trial. Many of them were from country areas, including some very isolated places, but some were from towns (25% of College members work in rural or semi-rural areas), covering most parts of Great Britain. Five had tape-recorders, the others had long-play record-players.

Material and Method

The first recording consisted of a 15-minute introductory talk describing the experiment, followed by a 15-minute talk on recent advances in virus disease. This subject was chosen as it has a distinct bearing on general practice and is likely to be thought "too technical" in print. Compared with later ones, it was not acoustically a good recording, was read from a script, and was very concentrated. The second also lasted 30 minutes and was a much better recording: an informal talk by a general practitioner on psychiatry in general practice, a subject for which there had been many requests. The talks were first recorded on tape, and, from this, soft disks were cut. (These are similar to commercial L.P. disks except that, being individually cut from shellac, small numbers can be ordered, whereas the more serviceable hard pressings have to be bought by the dozen at least.)

The listeners were divided into four groups: one group of doctors with tape-recorders, and three groups of those with gramophones. The tape or disk was sent to the first member of each group, who was asked to listen as soon as possible, and then post it to the next man on the list, the last returning it to us. In the package were included two envelopes: one, to be read before listening, gave general instructions and a description of the recording; the other, not to be opened until after listening, contained the following questions: (1) Did you find this more, or less, instructive than reading a similar talk? (2) Did you have difficulty in finding time to listen? (3) Be honest—would you have read this kind of article? (4) What length of recording would you prefer? (5) Suggestions for future recordings. (6) Any other comments.

Listeners were asked to reply to these questions in a letter to us when they posted on the recording, which also gave us a clue to its whereabouts. They were asked, if possible, to collect a group of colleagues to join them in listening and discussion.

With the second recording went a different set of questions: (1) Did you find this recording helpful? (2) We shall be making more detailed talks of psychiatry for loan on application—would you like to hear them? (3) How many doctors listened to this talk with you? This recording was sent out only on disk, and to 14 listeners at that time, although very many others have heard it since then, and it was used for the first tape-discussion.

Results

Of the 27 doctors who received the first recording, 18 found the method more instructive than reading, 4 less, and 3 were not sure. Four thought that it was easier to concentrate when listening than when reading, and two thought that the novelty had a lot to do with it.

Twenty-two said that they had not had much difficulty in finding time to listen, and five said it was not so easy. Some added the proviso that it was all right if they had four or five days. (In fact, few kept the recording for more than a few days. One circuit of eight doctors, including postage time, was completed in just over six weeks. During that time about half of the listeners managed to collect others to listen. This was, however, during January-March. Summer circuits are naturally taking much longer.)

Eleven would have read a similar article, 14 would not. But only one actually saw the article in print and read it—a very similar one was in several journals at this time—an example of false confidence in reading.

Thirty minutes was the most popular length.

A long and carefully thought out list of suggestions for future recordings was received, which was very similar to the requests for subjects for courses from the questionnaire replies, with much emphasis on recent advances, and new drugs.

The 14 replies to the second set of questions were uniformly monotonous. All who heard this (second) recording

found it helpful, all wanted to hear more, and 33 other doctors had listened, so that, on an average, each had gathered two or more friends for discussion.

Other Comments.—We were pleasantly surprised by the interest and enthusiasm aroused by this trial. We had many long letters full of every kind of advice, suggestions, and offers of help, besides comments and criticisms. Allowing for kindness towards a new venture, we had the impression that recorded talks would find a willing audience. We noted very soon a difference between the tape-recorder and gramophone listeners—the former being more trenchant, though more constructive, in their criticism, and wanting less formality and more "audience participation," while the latter were more conservative and perhaps less critical.

Conclusions From the Trial**Technical**

From this trial we learned a great deal, which may be summarized thus:

1. Soft disks, although fairly tough, are not equal to ordeal by G.P.O. Many were badly scratched, and after one was returned from the Highlands actually bent we decided to increase the number of our listeners to justify the expense of commercial pressings. Suitable postal containers remain a headache, but we hope to overcome this shortly.

2. Very good quality indeed is required if the recording is to be transferred from tape to disk. Without professional equipment it is impossible to make a good enough recording of a meeting or discussion in a public place, because acoustic conditions are usually bad. We have made many such recordings, but while they are satisfactory enough on tape, they will not do for the disk. We now record entirely, if possible, in ordinary living-rooms, which have the added advantage of putting the speaker more at his ease.

3. We soon found that any formality (such as reading from script) or artificiality of manner was mercilessly exposed by the microphone. To sound right, the talk must be informal, unscripted, almost "armchair." Some speakers can achieve this without effort, some perhaps never, and some rely very much on gesture or expression. One learns to recognize a good microphone speaker, and we are sure that there is a whole new field of talent awaiting discovery.

Non-technical

The response to this short trial encouraged us to believe that there was a demand for recorded talks, and we invited any interested members of the College to join in further experiment. Most of them would be able to listen only to disks, but a surprising number of doctors have tape-recorders, and many of them (like tape-recordists everywhere) have a great deal of energy and enthusiasm, and correspond on tape with others here and overseas. We hope to let them play a really active part in postgraduate education by joining in tape-discussions, recording their own cases for discussion, or by acting as "local correspondents," these being some of the ideas suggested by those taking part in the trial.

The Medical Recording Service at Present

This is now a regular service of the College of General Practitioners to its members, well over 100 of whom are now receiving recordings regularly. They are by no means all "geographically isolated," as many of them come from the great towns. The "circuit" system worked well during the trial and is still used, talks being sent round groups of about 10 members each every other month. Five talks have been completed and many others are in the making. About half are by consultants and half by general practitioners with a special interest or experience, titles and subjects being drawn at first from our original list of requests. Where possible, illustrations accompany the recording, either as duplicated diagrams or transparencies (a small pocket viewer is enclosed) to be studied while listening. For

example, one talk on skin disease is accompanied by a series of 24 transparencies and two diagrams.

Members on our list receive tapes or disks at regular intervals, but they can, on request, have a particular recording again, perhaps for a meeting, as can any other member of the College.

Also available on request to members are a number of recordings which will form the nucleus of our library. These include recordings of notable College occasions such as the James Mackenzie Lecture, and more detailed talks on subjects, such as more advanced psychiatry, which have been asked for by members but may not appeal to all.

The Discussion Tape.—This is a new feature of the service, which is still experimental. Accompanying each recorded talk to listeners with tape-recorders is a blank reel of tape. After hearing the lecture, each listener has five minutes of tape to record his own comments, ask questions, and air his views. This tape will go round a second time so that the earlier speakers can hear the whole discussion—that the earlier speakers can hear the original lecturer will answer the thing. In some cases the original lecturer will answer the questions and round off the discussion before the completed tape goes out again. This is a very popular idea, as even the shyest listener can have his say, without fear of interruption, with as much time as he likes for preparation. The following comments, taken from part of the first discussion tape, give some idea of the response.

"Two colleagues came 12 and 6 miles and felt it well worth while, and we had a stimulating discussion . . . the Medical Recording Service is doing a real service to medicine . . . unenlightened G.P.s can be shown the virtue of joining the College through the virtuosity of its members."

"This was a thoughtful and well-delivered address, and held my interest throughout. . . . The contributions of the others before me were of almost as much value as the lecture."

"My partner and I had a very enjoyable evening listening to the talk and discussing it."

"If I'd been the first . . . I think I'd have said I'd rather have read the lecture, but now I see how much better it would have been if I'd invited other doctors to listen with me. I hate psychiatry and fear mentally upset people, so to make up for it I used to read a lot, but it only made me feel more inferior. This talk has shown me that perhaps I've been approaching the subject in too highbrow a fashion. . . . You've done me a lot of good."

They all described their own problems and asked questions, comparing notes with one another. It is impossible to convey in print the excitement of hearing the voices of doctors, separated by hundreds of miles from the lecturer and from one another, discussing their reactions to a talk and intervals of time, they were together, and it should be remembered that tape, needing no processing and quickly copied, can be sent directly after a lecture or event to listeners anywhere, probably more quickly than it could be put into print.

Plans for the Future

Talks will continue to be sent out at regular intervals, and we shall hope to cover a large field of subjects. Our aim, however, will always be to direct attention to, and stimulate interest in, other methods of education, particularly discussion groups.

We are experimenting with recordings of heart sounds and other subjects, to see whether we can make use of them, as some subjects are more suitable than others, and an enormous amount of research on technical points needs to be done. We hope eventually to build up a comprehensive library for the College, so that any member will be able to obtain an up-to-date talk or course in any subject. Recordings of historical interest to the College will be collected for its archives.

We hope overseas members will be able not only to listen to our recordings, but to send us some of their own, so that real contact can be made with them.

In these ways we hope to advance a step further the work that the College has already done in bringing together its members and giving them a feeling of brotherhood and unity of purpose.

We thank Smith Kline and French Laboratories Ltd. for paying for the production costs of both the original trial and the present Medical Recording Service; and John Hassell Recordings for technical advice and help. Also the countless members of the College of General Practitioners whose enthusiasm and help made the idea become fact.

**PSYCHOLOGICAL MEDICINE IN
GENERAL PRACTICE****A REPORT PREPARED BY A WORKING
PARTY* OF THE COUNCIL OF THE COLLEGE
OF GENERAL PRACTITIONERS**

A working party of the Council of the College of General Practitioners was appointed to study psychological medicine in general practice, after a request had been received from the Ministry of Health for the views of the College on this subject. It accepted as a definition of *psychology* "The science which deals with the mind and mental processes," and of *psychiatry* "The recognition and treatment of diseases of the mind" (*Stedman's Medical Dictionary*).

First, written evidence was obtained from 27 members of the College who had expressed a special interest in psychology and psychological medicine in a general practitioner's work. Next, details of the teaching of these subjects were sought from all medical schools in the British Isles and from some in the Commonwealth. A draft report was then sent to the Association of Teachers of Psychiatry in Undergraduate Medical Schools, to members of the Psychological Medicine Committee of the British Medical Association, the Royal Medico-Psychological Association, and the Society for Psychosomatic Research, to all members of the Council of the College in the United Kingdom and Eire, to many consultant psychiatrists, and to others.

This report, which has now been submitted to the Ministry's Standing Advisory Committee on Mental Health, discusses the importance of this branch of medicine in general practice, and the types of psychological illness seen by family doctors; it examines the leading part that should be played by all family doctors in this work, and the undergraduate and postgraduate instruction they require; it points out the help that may be given by a general practitioner with a special interest in the subject, and his particular needs at present; and it makes six recommendations.

**Importance of Psychological Medicine in General
Practice**

Every good family doctor must be a good psychologist, for psychological medicine is part and parcel of all general practice. To misdiagnose organic disease has long been regarded as a serious error; it is now appreciated that to miss psychological illness is just as bad and may lead to even greater unhappiness. So much

*Members of the Working Party: Dr. C. A. H. Watts (Chairman); Dr. S. I. Abrahams (London) and Dr. J. H. Hunt (London) (joint honorary secretaries); Dr. Annis C. Gillie (London); Dr. J. P. Horder (London); Dr. Richard Scott (Edinburgh).

of medical teaching is concerned with organs and tissues that students, their teachers, and family doctors sometimes lose sight of the patient as a person whose anxieties, fears, griefs, rages, guilts, and inadequate relationships with other people can, and do, make him ill. When a person brings such a trouble to his doctor, both of them at first may be genuinely unaware that it is related to emotional upset, the significance of which may emerge only during treatment. All medical training should convince students that the person who is ill is as important as the illness from which he suffers, and that the kind of doctor is often as important as the kind of patient he is treating (Bomford, 1958). Psychological illness is one of the most pressing matters confronting the medical profession to-day; in this report only those aspects of it which are of special significance to general practitioners are considered.

The psychological problems which confront family doctors have been listed by the working party. One difficulty in compiling such a list is lack of a common classification; another is that any assessment of their incidence can only be approximately correct. The percentage of people reported with psychological illness in any general practice depends not only on the type of practice but also on the assessor, his diagnostic skill and criteria, and on his attitude towards his patients. Pemberton (1949) found 6.5% and Paulett (1956) 70% over a five-year period, while the generally accepted figure is in the region of 30%. The true incidence is probably more uniform from one practice to another than these studies suggest. The more we attempt to elucidate this subject the more impressed are we by its purely quantitative aspects.

Types of Psychological Illness Seen in General Practice

Psychological illnesses seen by family doctors fall into five main groups, which frequently overlap.

1. Anxiety and Depression from Emotional Stress

All people suffer from transient anxiety and depressive states due to the inevitable bereavements, disappointments, stresses, and strains of life. They usually get over them on their own, helped perhaps by the sympathetic understanding of a relative, friend, or minister of religion. Many symptoms are produced by such emotional upsets, from headaches, insomnia, or palpitations to anything else of which a patient may possibly complain. In children, behaviour disorders—from tantrums to truancy—often take the place of subjective symptoms; their understanding and treatment are an important part of general practice. Every organic illness has its natural psychological component, which may be mild and hardly noticed or severe; some are more likely than others to be accompanied by superadded emotional upset—for example, cancer, venereal disease, arthritis, heart attack, or stroke. Certain symptoms are particularly prone to cause reactive anxiety or depression, such as pain, bleeding, a lump, failing vision, deafness, or infertility. Influenza, sinusitis, and jaundice are sometimes associated with, or followed by, an unusual degree of depression, which also occurs after treatment with certain drugs (sulphonamides, reserpine), and after deep x-ray therapy. Rehabilitation following any serious injury or illness brings its own emotional problems.

2. Constitutional Liability to Anxiety or Depression

When some sensitive and imaginative people are subjected to stress they may develop anxiety or depres-

sive symptoms which last longer than normal. This group embraces not only the weaklings but also many of the outstanding thinkers, leaders, scientists, doctors, teachers, artists, musicians, poets, lawyers, and churchmen of every generation. When stress produces incapacitating symptoms for a long time, or when these develop without adequate cause, there is often evidence of some degree of inherited nervous predisposition. Mild endogenous depression developing insidiously, with symptoms which may be referred to any part of the body, is one of the commonest psychological disorders met in general practice. It gives rise to much transient disability and unhappiness; it responds well to modern treatment; and yet not to recognize it, or to mistake it for organic disease, is possibly the most frequent diagnostic error made in medicine to-day. Some hypochondriacal and obsessional states (with phobias) also fall into this group. Other people suffer from illnesses on the borderline between physical and psychological disturbance—premenstrual tension, spastic colon, ulcerative colitis, asthma, or eczema. The aetiology of these is often partly constitutional and partly bound up with emotional state. It must never be forgotten that mind and body are interrelated and interdependent components of the whole, and that emotional conflict has profound effects on function and physical condition, and vice versa. The constitutional nature of many of these disorders must be clearly recognized. In the present state of our knowledge many of these people have to be supported and managed by their family doctors, rather than cured, so as to make life tolerable not only for the patients themselves but also for their families, neighbours, and all others associated with them.

Mild episodes of stress disorder do not require skilled psychiatric attention, any more than do the slight bruises and strains received in everyday life need the care of an orthopaedic surgeon. When symptoms are severe, however, expert psychological treatment may be wanted. Not every doctor likes this kind of work or is temperamentally suited to it; many have not had appropriate training or experience; and some deliberately avoid it, for they find such patients time-consuming, embarrassing, boring, or just "difficult." Such likes and dislikes apply also to other branches of medicine. Some family doctors, on the other hand, have a special aptitude for psychological treatment which patients soon recognize and appreciate; and much of this work is well within the scope of general practitioners who are interested and have been trained in this subject. Many experienced family physicians, in the past and to-day, have taught themselves the art of how best to handle these patients, often highly successfully. Younger doctors can now be greatly helped by proper undergraduate and postgraduate instruction.

3. Other Constitutional Personality and Behaviour Difficulties

The majority of personality upsets and behaviour difficulties met in general practice lie on the fringe of normality; but they have to be recognized and taken into full account by a general practitioner trying to assess and manage an ill person. When more severe they include antisocial behaviour and delinquency, alcoholism and other addictions, sexual perversion, and hysteria in all its manifestations. Most of these need specialist advice and treatment, but not all can be cured; many of the remainder, when they ask for help, can be usefully supported over long periods by their family doctors.

4. Organic Brain Disease

The management in their homes of patients with psychological symptoms associated with organic disorder of the brain (after head injury, in epilepsy, in mentally subnormal children, arteriosclerosis, cerebral tumours, and so on) is another important part of a general practitioner's work.

5. Psychoses

Schizophrenia, severe manic-depressive psychosis, and the psychotic later stages of many organic cerebral diseases are comparatively rare in general practice; but the unique part that a general practitioner can play in their early recognition may be of supreme importance both to the patient and to his family. Involutional depression and arteriosclerotic senile dementia are by no means uncommon, and may be a heavy burden on a busy doctor, especially in patients who prove uncooperative or suspicious. In future it is likely that a larger proportion of patients in mental hospitals may be helped enough by modern treatment to be returned to their homes under the care of their general practitioners.

Psychological Medicine in the Work of all Family Doctors

In the treatment of people with psychological illness every general practitioner starts with an advantage over the consultant because of his knowledge of his patients and the background against which they live their lives, his accessibility to their families, and the continuity of his contact, perhaps over generations. He is the person best fitted to manage the great majority of psychological ailments. His predecessor, the old-time family physician, with his common-sense approach, did extremely well in this field as confidant, counsellor, and supporter of the families under his care. To-day the general practitioner's opportunities are still unique, patients and to help them psychologically are still unique, especially in country practices where he is part of their environment. He lives among them, and has many close ties with them. He knows their family histories and past histories; he may be present when they are born, married, or dying; he examines them in his surgery or visits their homes when they are sick; he sees them at work and at play; and he knows how they usually behave. In course of time he may learn much about their characters and personalities, troubles and anxieties, sympathies and affections, responsibilities and ambitions, and their habits with regard to smoking, alcohol, and medicines; and he probably knows something about their morals.

A good family doctor, with this background of continuing friendly interest in the lives of his patients, can listen with understanding and consideration while they talk freely about their difficulties. By sympathetic explanation, reassurance, advice, and support, and with suitable medicinal treatment, he can, by himself, help them enormously. The first interview in any illness is often the most important. Sometimes a full physical examination is required before reassurance can be given; although, when the basis of the trouble is clearly emotional, much may be gained by indicating this to the patient at the outset. Expert listening will comfort many worried people; and repeated or extended interviews may perhaps be needed to enable some patients to work through their various problems. This simple psychotherapy and the privilege of this intimate personal doctor-patient relationship, with its mutual trust, affection, and confidence, has always been and will always be cherished by both patients and their family medical advisers. It may take up time which cannot readily be spared; but, if the emotional nature of the illness is not recognized, quite as much time, or even more, may be spent over the years trying to control a hypothetical, non-existent organic disorder.

There are certain limitations to this relationship which should be clearly appreciated. In large town and city practices, with enormous lists and nomadic populations, it is impossible to attain the ideal expressed above; but the better the doctor the nearer he approaches it. However friendly a family doctor may be with his patients, it sometimes happens that they fail to enlarge on their private worries, and keep much deeply hidden for years. The very closeness of a general practitioner to other members of a patient's family or friends, especially if they mingle in the same social set, will often be a bar to the revelation of embarrassing feelings or events which the patient may prefer to discuss with a complete stranger. For instance, a young woman may not disclose frankly a personal difficulty because her general practitioner may be thought to be too nearly identified with the points of view of her parents; she may prefer to take her problem to another. No doctor should feel hurt if a patient decides to discuss a private problem with a more distant, neutral adviser.

The family doctor has many allies in this field, and if he fails to make the best use of them he will provide less than the optimum service to his patients. They include his partners, assistants, and consultants; the patient's relatives, friends, or employer; medical officers of health; psychiatric and other social workers, State-registered nurses, health visitors, midwives, and almoners; domiciliary occupational therapists, physiotherapists, home helps, and citizens' advice bureaux; the clergy, teachers, marriage guidance counsellors, and qualified lay psychologists; duly authorized officers, probation officers, and the local representatives of a great variety of other statutory and voluntary social organizations. Every attempt should be made to link up general practice with these social and other services. Some patients will derive more benefit from them than will others. Everyone realizes that school problems can often be settled by consultation with a teacher, and the educational psychological service can be of great value in managing these difficulties in children. Sometimes it is only the minister of religion who has access to a person's confidence; religious faith can play a large part in helping many people.

The family doctor needs to have more than a nodding acquaintance with this vast army of potential colleagues. He must know something of them all, and develop special skills and techniques in establishing good relations with them, and in working with them as a team. The development of team skills has received much less formal attention in general practice than it has in hospital medicine. A general practitioner should make use of everything and everyone who can help to modify his patient's environment for the better, or at least to mitigate some of the adverse factors in it; to marshal the resources of family and State in order to aid and rehabilitate the patient, and to reintegrate him into the community to which he belongs. A change in a patient's attitude to his social environment or personal relationships is needed far more often than a variation in blood chemistry by the use of drugs; but unfortunately such a change is often impossible, and then a person may need support, perhaps over many years, from his family doctor and the social services. In the development of these team skills the general practitioner can operate most effectively if he retains control and accepts the challenge of responsibility and leadership, taking it upon himself to introduce his patients and interpret their needs to his various helpers. Sometimes it is his duty to protect those under his care from a superfluity of opinions and advice.

Responsibility for mental health in this country, in future, will rest more and more on the general practitioner. A great deal remains to be done before he is skilled enough, and adequately equipped, to do the good work in this field of which he should be capable. There are encouraging signs already of a closer liaison, better understanding, and a new pattern of co-operation between him, his psychiatric specialist colleagues, and a great variety of social agencies. The development of this team-work in the National Health Service will ensure the best use of community resources which have, so far, been inadequately tapped.

We have discussed how much of the family doctor's work is taken up by psychological disorders, many of them on the fringe of normality, and how well he is placed for their prevention, diagnosis, and management. We have pointed out how much good in this field every general practitioner can do himself, and on other occasions how much he and his patients benefit when he co-operates, in a team, with his many potential helpers from the social services. We have shown how advantageous it may be for a group of doctors to have one partner who, though still primarily in general practice, has been specially trained and experienced in this branch of medicine, and how much he can teach his colleagues. With increasing understanding by all general practitioners, and by the public, of the significance of anxiety and stress in health and disease, and with advances in knowledge and skill of succeeding generations of family doctors, the average standard of work in this field should be very much higher in twenty years' time than it is to-day.

Recommendations

We recommend that:

1. In the undergraduate medical curriculum greater emphasis should be laid on normal psychology and on psychological medicine.
2. In qualifying examinations there should more often be a compulsory written question (or its equivalent in the clinical or oral) on the psychological aspect of medicine, and one of the examiners should be interested in this subject.
3. More postgraduate training of general practitioners in psychological medicine should be arranged in all areas.
4. In helping their patients with psychological illnesses more opportunities should be taken by family doctors

THE PHYSICIAN AND HEALTH EDUCATION

BY

GUY W. STEUART, M.A., M.Ed., M.P.H.
Senior Lecturer, Department of Social, Preventive, and Family Medicine, University of Natal; Organizer, Health Education, Institute of Family and Community Health, Durban

The clinical situation, with its intimate doctor-patient relationship, is a peculiarly appropriate one for health education. Yet it is probably true to say that the physician has not adequately exploited his unusual educational opportunities. There are still far too many people who make relatively frequent use of their doctors but who remain with little knowledge and insight into their own states of health or those of their children. The numbers are legion indeed of those who have done little more than acquire a few esoteric terms to spice their conversations and impress their friends.

The Patient's Viewpoint and Physician's Role

To consult his doctor is, on the part of the patient, usually a decision of surrender. Even with mild complaints he feels that he can no longer carry on alone. Under a threat to his security, his immediate need is not to think for himself but rather to confide in someone who will take over a responsibility he can no longer bear.

The greater his anxiety, the more receptive is he likely to be to an authority and decisiveness that offers to restore

to develop team-work with the ancillary services, to all of which they should have free access; and the Ministry of Health should give more encouragement, and assistance, towards linking general practice with the social services.

5. The Ministry of Health and other appropriate bodies should investigate the possibility of giving more opportunities, and recognition, to general practitioners with a special interest in psychological medicine who have had training and experience in it.

6. In the future development of the National Health Service the fundamental role of the general practitioner, in psychological medicine as in other branches of medicine, should be recognized.

Grateful acknowledgment is made to the 37 psychiatrists and other consultants who have helped the working party in the preparation of this report; to the heads of the psychological departments of all the teaching hospitals in the United Kingdom and Eire, and of some in the Commonwealth; to the members of Council of the College of General Practitioners; and to the following practitioners who have expressed a special interest in psychological medicine and who have given much helpful advice: Drs. F. A. Bevan, T. S. Beveridge, F. M. Brook, J. F. Burdon, J. M. Clow, E. G. Cohen, D. Craddock, W. V. Cruden, J. A. Currie, B. J. Foster, A. Fry, R. N. R. Grant, E. C. Hamlyn, Marjory C. Hogg, P. Hopkins, C. E. Langley, M. J. Linnett, F. A. Lodge, E. V. Mackay, A. U. MacKinnon, M. Marcus, A. Model, J. G. Ollerenshaw, H. S. Pasmore, Jean W. D. Pasmore, R. A. B. Rorie, P. Rowntree, J. A. Taylor, H. E. Thorn, D. Iona Troup, and J. Whitby. The particular thanks of the working party are due to Mrs. D. I. Phillips, who has most patiently undertaken the typing and circulating of many drafts of this report.

something of certainty and orderliness to his life. Thus, although in one sense he is highly susceptible to suggestion, he is also, paradoxically enough, rather ineducable because the fundamental understanding and insight that marks sound education is not what he primarily wants.

He is seeking essentially a short-cut solution to his problem. His dominating motive is to hand over his troubles to an expert in whom he has some measure of faith. But of this expert's hidden store of skills he has little comprehension, and within limits he is emotionally set for an uncritical acceptance of what he is told.

To this extent he is in psychological continuity with all the patients of medical history who have endowed their healers with magical powers.

The physician thus finds himself in a mould, pre-cast by his patients and by society, and he would be more than human if he did not find the proffered role somewhat tempting. Not only does he himself find it satisfying in the shortest possible time to establish an unequivocal diagnosis and a clear regimen, but it is certainly demanded by his patients.

The physician's conclusions may be medically quite valid, but while he retains too much of the aura of authority he limits more than he need the patient's understanding both of his diagnosis and of his therapy. The patient comes away with that mysterious justification for his future behaviour, both rational and irrational, significantly called "doctor's orders." Thus, once he has had his complaint labelled and has been told to take a tablet at certain times, to change his diet, or to rest more often, this may mean little more to him than the anxiety-relieving rituals of magic to a primitive.

Thus, with the physician in an active dominating role and the patient in a passive dependent one, we have a contradiction of the best educational situations where the learner actively and intelligently participates in solving his own problems and meeting his own needs.

Moreover, the somewhat undignified dependence of the patient often means that, as he recovers and his feeling of independence is restored, while gaining a greater respect for himself, he tends to lose it for his regimen. It is therefore not uncommon to find the patient, in his final stages of recovery, avoiding desirable contact with his doctor and neglecting the advice he received.

The result is that considerable numbers of patients resume their daily rounds as before, having received only a short didactic training in a limited mechanical procedure that has little meaning for them.

Why Educate the Patient?

Of course, we may well ask why the patient should receive a broader guidance and education. After all, he presents a complaint to his doctor and at least his immediate need is met when this is ameliorated.

But it is hard to conceive even of a frankly curative service as being desirably concerned only with cures. Such a feat of purism would be difficult to defend. Curative services may begin with cures, but they surely should not end with them. They are intimately concerned with the future of the patient in respect both of the prevention of disease in the future as well as of the positive promotion of his health. In these respects, at least, the patient has a heavy personal responsibility which he cannot adequately fulfil without education.

Moreover, it is no longer possible for us to take refuge in a theory that with medical advances there shall be revealed more highly specific aetiologies that will enable the physician to treat and prevent disease through technical acts of extraordinary precision with less and less need for personal guidance of the patient.

It is a naive conception indeed that the function of science is primarily to simplify. On the contrary, its function of revealing new possibilities and of vastly complicating our vision of things is of at least equal importance. There is hardly room to-day for beliefs like those of Crookshank's (1920) ingenuous police surgeon, who declared that "bullets are the cause of war, as of murder."

In point of fact, recent advances in medicine have increased immeasurably the stature of emotional, behavioural, and social factors in the aetiology of disease and the maintenance of health. The vital role of human relationships; of emotional adjustment; of habits of sanitation, diet, smoking, drinking, sleep, work, rest, and exercise; of attitudes to and the use made of health and medical services—indeed, of the total pattern of the individual's daily life—has acquired a significance impossible to ignore.

The individual's personal influence on his own health is therefore of unusual importance. He can receive only limited help from the physician who remains narrowly preoccupied with the physical and biochemical aspects of disease and with the immediate technical expert acts he can perform on behalf of his patient. Such an approach misses one of the greatest potentialities of the clinical situation in guiding and educating the patient in his own care.

In the words of Delore (quoted by Mackintosh, 1953): "Over and above each technical act there is a corresponding educational function which doubles the value of the act, prolongs it, increases its efficiency and endows it with real human and social value."

It seems high time, then, that we take more vigorous action to fashion the physician's role in a form more consonant with his possible educational function.

Desirable Steps

To achieve this end there are perhaps two major aspects of patient management that require attention. The first is the need for the physician to develop and exploit a more

psychiatric type of relationship than is at present current. This would include greater opportunities for self-expression by the patient and consequently a more passive and permissive role for the doctor, in which his interventions were not only explanatory but suggestive and co-operative rather than didactic and authoritarian. In such a clinical context his guidance could be more closely related to the felt and expressed needs of his patient. This would enable him to build on the essential foundation of the patient's interpretation of his own problem and not so much on a discrete medical interpretation meaningful only to himself. It would enable him to adapt his guidance more easily to the individual patient's peculiar habits, attitudes, feelings, and knowledge as well as to the particular degree of that patient's emotional rigidity and resistance to change.

Secondly, the physician should be more actively aware of the need to salvage the patient's capacity for independence and to build up his self-reliance and confidence. This is not to say that when the patient appeals for help the physician should throw him back on his own resources, but rather that as early as possible the physician should encourage the patient to feel that he has control over his own destiny and that he has an intelligent role to play in his treatment and in the future care of his own health.

It is in such a context that the patient may be given information to the extent that his motivation and understanding permits—which is somewhat further than most doctors are inclined to assume for most patients. This is, of course, not an entirely easy proposition, for what profession is there whose public prestige is more enhanced by the full-dress regalia of its technical jargon? Indeed, it is probably a need of most physicians that they learn to express medical principles in terms which are both accurate and comprehensible to the increasingly well-educated public of modern times.

If these suggestions are valid it is apparent that the problem of educating the patient is not a matter of simple accretion of an extra element, but rather of a reorientation of the whole clinical situation and of the doctor-patient relationship.

Possible Objections

There are naturally certain objections which may be raised. It might, for example, be said that the busy medical practitioner is at present hard pressed enough—too hard pressed, perhaps—to give each of his patients sufficient time. He would therefore be unlikely to welcome the introduction of procedures which may considerably lengthen his clinical contact with the patient.

To counter this it may not be unreasonable to claim that in many practices short-term palliative treatment, on the one hand, and pressure from numbers of patients whose care and guidance have not been thorough enough in the past on the other, are parts of the same vicious circle.

But even if this was not wholly true, the fact remains that education and guidance techniques are clinical skills like any others. As such they require careful teaching and considerable experience. While the application of the principles by a beginner may appreciably lengthen his clinical contacts, we have no reliable estimate of the short-term, let alone the long-term, implications for time, once the practitioner is really skilled.

Each physician must remain the judge of what he can best do under the circumstances and demands of his practice. In the last resort, however, there is no blinking the fact that some balance (in spite of periodic changes in the centre of gravity) must be found between the needs of time economy and the needs of optimal medical efficiency.

Another objection might be that education of the patient frequently means giving him information which he will misinterpret or which may affect his clinical condition adversely. It is quite obvious that this again is a matter to be decided by the physician with each patient, and is a vital and intrinsic part of his clinical judgment. But in the long run it is hard to defend the withholding of information outside of the exceptional case. Quite apart

from the critical question of whether it is morally defensible, there are essentially practical reasons.

To-day, when people have reached an unprecedented level of literacy and education, and have an almost unlimited access to a wide variety of sources of information about health and disease, this whole objection loses force. Whether we like it or not, patients are going to have their questions answered with varying degrees of accuracy by friends and relatives, by quacks of all kinds, by articles in newspapers and popular magazines, and by commercial advertisements.

It is therefore clearly in the interest both of the physician and of his patient that the latter should not leave his doctor with questions he would like to have asked but did not, or with answers that did not satisfy him. It seems an elementary insistence that the patient is entitled to know all his doctor can tell him and that his doctor is the best person to tell him.

Medical Education

The ultimate solution of the problem, as of many others affecting modern medicine, probably lies in the field of basic medical education. There is to-day a clearly discernible increase in appreciation of the fundamental need of medicine to be systematically moulded into a more human and social discipline and to widen its interest in diseases to include the people and communities that suffer from them.

Medical education may, after all, be designed to produce physicians who not only have the technical knowledge and skills of their craft, who not only see health and disease as a by-product of personal and social life, but who are at once humane and imaginative educators as well.

SOME POPULAR BELIEFS CONCERNING THE CAUSES OF CANCER

BY

ANN CARTWRIGHT, B.Sc.

AND

F. M. MARTIN, B.A., Ph.D.

Lecturers, Department of Public Health and Social Medicine, University of Edinburgh

It is difficult to assess with any precision the present balance of medical opinion on the value of cancer education. A questionnaire circulated a few years ago by the British Empire Cancer Campaign drew replies from only one-quarter of the general practitioners to whom it was addressed, and of these slightly more than half expressed opposition to education of the public concerning cancer (Horder, 1953). More recently, however, it has been shown (Wakefield and Davison, 1958) that a carefully conducted local programme of cancer education can in practice gain the widespread approval of general practitioners. At the same time, the increasing volume of evidence tending to incriminate cigarette smoking as a major factor in the aetiology of cancer of the lung has stimulated the interest of many medical practitioners in the possibilities of education or propagandist activities directed towards a reduction in the incidence of what would appear to be an eminently preventable disease.

The planning of health education in this field, if its desirability be accepted, is likely to be the more effective if it takes account of the prevailing patterns of belief

and habit in the community. In this context, the findings of a recent inquiry, which throw some light on lay beliefs concerning the causes of cancer, with particular reference to the role of cigarette smoking, may perhaps be of interest.

The data presented here were obtained through interviews with a random sample of the adult population of the City of Edinburgh. The background of the inquiry, the sampling procedure, and the response rate have been described elsewhere (Cartwright, Martin, and Thomson, 1958). The inquiry was primarily concerned with popular beliefs concerning tuberculosis, but certain questions about cancer were included in the interview.

General Attitudes Concerning Cancer

Some indication of popular fears of cancer in comparison with other diseases is provided by replies to the opening questions of the interview, in which our subjects were asked what illness they thought was most dangerous for children under the age of 15, for adults under the age of 45, and for adults over that age. Only one person in a hundred mentioned cancer as the most dangerous disease for children, but a quarter and a third respectively thought it was the most dangerous illness for adults below and above the age of 45. In each of these last two groups cancer was the second most frequently mentioned disease; tuberculosis (29%) was specified slightly more frequently for younger, and heart disease (34%) slightly more frequently for older, adults.

There were, however, no indications, at any rate at the level of conscious awareness, of a widespread incidence of what is sometimes referred to as cancerphobia. Less than one-third of the people questioned said in reply to a specific inquiry that they were worried about their own health or the health of any member of their family, and of these the majority were concerned about some illness present at the time. Among those who expressed anxiety about an illness not actually present cancer was the disease most frequently mentioned, but even this was named only by one person in fifty.

When asked which of five selected causes of death was responsible for the greatest number of deaths, 35% of our subjects said heart disease, 32% street accidents, and 27% cancer. Only 5% cited lung tuberculosis and 1% poliomyelitis. Cancer was much more often specified by women (35%) than by men (18%). Asked to estimate whether death or recovery was the more probable outcome in each of the four diseases included in the previous list, the members of our sample were least optimistic about the prognosis for the cancer patient, with three-quarters thinking death the more likely outcome. One subject in five, however, thought that a person who had contracted cancer was more likely to recover than to die.

A somewhat higher proportion, nearly one-third, said they would rather not know if they had cancer, even though, in answer to a later question, only 9% thought the chances of recovery were not improved by early diagnosis. For lung tuberculosis people were apparently more convinced of the value of early diagnosis; only 2% thought it would not improve the chances of recovery, and only one in ten said they would rather not know if they had it.

Beliefs About the Causes of Cancer

In an attempt to discover the pattern of popular beliefs about the causes of cancer, we first asked a general question in which we did not suggest any possible cause. Replies have been classified into various groups in Table I.

The cause most frequently suggested was knocks, bumps, or bruises; then in descending order of frequency came smoking; air pollution, fumes or dirt; inheritance; and tiredness, worry, overstrain, or frustration. The popularity of the belief that trivial injuries may cause cancer provides an interesting example of the psychological process referred

TABLE I.—Causes to Which Cancer is Attributed

Knocks/bumps/bruises	25%
Smoking	22%
Air pollution/fumes/dirt	14%
Inheritance from parents	8%
Tiredness/worry/overstrain/frustration	4%
Replies connected with food	4%
Infection	1%
Others	19%
No opinion	34%
Sample	554 = 100%

to elsewhere as "reduction to the familiar" (Cartwright *et al.*, 1958)—the tendency to relate the aetiology of major diseases to simple, everyday conditions; a parallel and even more widely held belief is that tuberculosis develops from neglected colds.

Only 1% of those questioned spontaneously mentioned infection as a "cause" of cancer, but when asked specifically about this another 12% said they thought it was possible to "catch cancer from other people." Rather similar questions were asked about the inheritance of cancer. This had already been mentioned spontaneously by 8%, and another 25% replied positively when asked about this specifically; one-third of these gave unqualified replies, and the remainder said that they thought a tendency to contract cancer could be inherited.

Members of the sample who had not previously mentioned smoking were asked whether they had heard that some doctors and scientists thought that people who smoked were more likely to get cancer than people who did not smoke; more likely to get cancer than their own opinion. The results are shown in Table II. Although most people had heard of the relationship, more than one-third of them thought that smokers were not more likely to contract cancer than non-smokers.

TABLE II.—Beliefs of 554 Persons About Smoking as a Cause of Cancer

Smoking mentioned spontaneously as a cause	75%	22%
Has heard of possible relationship	39%	78%
Has not heard of possible relationship		
Thought smokers more likely to contract cancer	30%	78%
Thought smokers not more likely to contract cancer	36%	
No opinion	12%	

Variation in Beliefs with Age, Sex, and Social Class of the Individual

Appreciably more men than women mentioned air pollution, fumes, or dirt as a cause of cancer (22% against 8%), and slightly more men than women mentioned smoking spontaneously. However, when they were asked specifically about smoking the proportion of men who thought smokers were not more likely to get cancer than non-smokers was 41% compared with 32% for women. Rather more women than men mentioned knocks as a cause of cancer (28% compared with 22%).

When we consider variations with age we find that the proportion suggesting knocks as a cause of cancer increases with the age of the person, rising from 18% for those aged 21-34 to 33% for those aged 65 or more. In contrast the proportion mentioning air pollution declines with age. The proportion thinking smoking, inheritance, or infection a cause of cancer when they were asked about these factors specifically was highest for the people over 65—probably because this group is the most willing to accept suggestions of this sort uncritically.

Social class variations reveal surprisingly few differences. The proportion mentioning knocks (17%) and highest professional and intermediate occupations (17%) and highest for those in unskilled manual jobs, but no consistent variation can be observed when we consider smoking as a cause of cancer, and there is little variation in the proportion mentioning air pollution, fumes, or dirt.

Smoking Habits and their Relation to Beliefs on Smoking as a Cause of Cancer

The proportion spontaneously mentioning smoking as a cause of cancer did not vary significantly between smokers,

non-smokers, and people who had given up smoking; neither did the proportion who had heard of the relationship. However, when we asked people who had not mentioned smoking as a possible cause of cancer what they thought about the theory striking differences emerged.

Nearly half the people now smoking said they did not believe that smokers were more likely to get cancer than non-smokers. This was more than twice as high as the proportion of non-smokers who held this view. It might have been expected that the people who had given up smoking

TABLE III.—Relationship Between Smoking Habits and Beliefs About Smoking as a Cause of Cancer

	Smoke Now			Given up Smoking	Never Smoked
	20 a Day or More	Less than 20	All those Smoking Now*		
	%	%	%	%	%
Smoking mentioned spontaneously as a cause	24	23	23	18	22
Had heard of possible relationship	72	74	73	81	75
Had not heard of possible relationship	4	3	4	1	3
Thought smokers more likely to get cancer	17	25	22	38	40
Thought smokers not more likely to get cancer	51	45	47	32	21
Don't know	8	7	8	12	17
No. of individuals = 100%	109	164	288	76	187

* Including 10 pipe smokers and 5 people for whom the quantity was not known.

were those who believed most firmly in the relationship, but in fact this group fell in between the smokers and non-smokers in this respect. The reasons of 76 persons for giving up smoking were then examined. These were: expense, 39%; health reasons, 37%; others, 20%; no answers, 4%. Expense and health were the reasons most frequently put forward for giving up smoking, but when the beliefs about smoking as a cause of cancer are examined for the small group of 28 people who gave up smoking for health reasons we find no significant differences between them and the other members of our sample.

The absence of any relationship becomes clearer when the health reasons in question are examined in detail. Only 2 of the 28 individuals concerned had given up smoking because of a fear of cancer; this may be compared with 14 who gave up smoking as a result of major or minor respiratory conditions, 3 because of gastric illnesses, and another 2 with cardiac conditions. It is evident that even among those who claim to have given up smoking for health reasons fear of cancer of the lung has played a very small part.

Conclusions

It is clear that smoking is now quite widely believed to be a cause of cancer. In an inquiry conducted in the Manchester area four years before our own (Paterson and Aitken-Swan, 1954), only 2% of those questioned spoke spontaneously of smoking when asked about the causes of cancer. By 1957 the corresponding percentage among the Edinburgh population had risen to 22, and when asked specifically another 30% agreed that smoking was a possible cause. It would seem that recent suggestions, in Parliament and elsewhere, that the Government should give widespread publicity to the association between lung cancer and cigarette smoking may be misconceived, since only three people in a hundred were not aware that such a relationship had been asserted. The problem is not so much one of knowledge as of conviction and action, and our findings demonstrate once again the fallacy of the Socratic assumption that underlies much health education.

Heavy smokers, though they were as likely as anyone else to know that an association between smoking and lung cancer had been postulated, were far more ready than non-smokers to deny the validity of the evidence. In short, their

expressed beliefs were largely a rationalization of their habits, while those who had never taken up smoking were correspondingly more prepared to attribute harmful effects to the cigarette. But if there is a gap between knowledge and belief there is also a gap between belief and action, for it is noteworthy that two-fifths even of the heavy smokers were prepared to accept the proposition that smokers ran a greater risk of contracting lung cancer. Among the motives of those who had given up smoking, fear of cancer played an insignificant part. To base one's beliefs on one's habits, rather than the reverse, is a characteristic not restricted to laymen. Pyke (1955) has shown that medical practitioners are no less irrational in their assessment of the evidence in question: 71% of non-smoking doctors were satisfied with the evidence linking cigarette smoking with carcinoma of the bronchus, but only 46% of the doctors who smoked cigarettes thought the evidence adequate.

The logic of the individual in our sample who said that if doctors believed in the association they would give up smoking, seems somewhat unjustified.

Public action directed towards the reduction of cigarette smoking may take one of two major forms. The first of these is the introduction of deterrents, of which the most obvious would be a further heavy increase in the excise duty on cigarette tobacco; this would probably have some effect, since the number of people who give up smoking on grounds of expense is already greater than the number who give it up for health reasons of any kind; but its precise effect would depend not only on the extent of the increase but also on future trends in income levels and in the relative attractiveness of alternative objects of expenditure. The other possible approach is educational. It is obvious that a mere exposition of facts is unlikely to be effective in persuading confirmed smokers to give up the habit, though it may dissuade some young people forming the habit. It seems to us that if educational activity is to be effective it must be based upon direct study of the habit of cigarette smoking—of the processes by which it takes root, the satisfaction which it yields, and the difficulty of giving it up. This is a subject on which we are aware of a number of hypotheses, but of little objective evidence.

ATTITUDES OF THE GENERAL PUBLIC TO MENTAL ILLNESS

BY

G. M. CARSTAIRS, M.B., M.R.C.P.Ed., D.P.M.

AND

J. K. WING, M.B., B.S., D.P.M.

Medical Research Council Social Psychiatry Research Unit,
Institute of Psychiatry, Maudsley Hospital, London

Although it is very likely that the attitudes of members of the general public towards mental illnesses have an important bearing upon the recognition and treatment of these conditions, few systematic investigations of such attitudes have been carried out, and all of these in the United States of America or Canada (Ramsey and Seipp, 1948; Roper, 1950; Woodward, 1951; Star, 1952; Cumming, 1955; Redlich *et al.*, 1955). Recently an opportunity presented itself to make some similar observations in this country.

In January, 1957, the B.B.C. broadcast a series of five television programmes under the general title of the

"Hurt Mind" which dealt with various problems connected with the aetiology, nature, and treatment of mental illness. Each of the broadcasts in the series was seen by approximately 15% of the adult population in the United Kingdom, equivalent to about 5½ million people. An attempt was made to measure some of the change in attitudes of the viewing public which could be attributed to seeing the programmes. The results have been reviewed by Dr. W. A. Belson, of the B.B.C. Audience Research Department, who found that a great majority of viewers drew a distinction between mental illness and insanity; many were unwilling to accept the ex-patient in certain occupational and other roles, and there was a general feeling that mental illness was something to keep quiet about. Little change was brought about in viewers' opinions in these respects. However, the series "increased somewhat viewers' knowledge on the subject of mental illness, especially in respect of methods of treatment. There was a moderate but broadly based increase in viewers' confidence in the ability of medical men to cure mental illness. . . . There was a small but well-spread increase in the viewers' willingness to associate with the ex-patient. . . ." (Belson, 1957).

When the "Hurt Mind" series was in preparation a preliminary survey of the "target audience" for these programmes was made. Groups of viewers, drawn from the Greater London area, were invited to Broadcasting House and there asked to fill in a written questionnaire, to ascertain their ideas about mental illness and its treatment, and their attitudes towards the mentally ill. One hundred and eighty people were involved, but this number was reduced to 167 in order to match the viewing public of Greater London in terms of a social level and age. This material was kindly made available to us by the B.B.C., who also permitted us to carry out a content-analysis of 1,267 letters written to the B.B.C. by viewers in response to the "Hurt Mind" programmes.

I. Spontaneous Opinions About Mental Illness

At the onset of the preliminary inquiry the 167 volunteers were asked to write as fully as possible what they understood by the expression, "A person who is mentally ill." The following content-analysis is based upon the answers to this question.

Major Diagnostic Categories.—Seventy-two persons seemed to be describing a psychiatric condition only, and 24 a neurosis or personality disorder only, while 23 seemed to have both in mind when thinking of mental illness. Of those whose answers were classifiable in this way, 80% mentioned psychotic traits or syndromes in their answers, and 40% mentioned neuroses. Only four answers seemed to describe mental deficiency.

Topics most frequently mentioned.—Each answer was then broken down into a series of separate statements. The most popular single item was an expression of general good will such as "needs much help, understanding, and kindness." Forty-five individuals (27%) replied in this way. Other fairly popular responses (mentioned by more than 20 people) were: "Due to worry, mental strain," etc.; "Sometimes violent"; "Needs to be supervised in an institution"; "Behaves or reacts abnormally"; "Pessimistic, depressed," etc. There were 665 separate items, of which 572 could broadly be classified under the headings Descriptive, Aetiological, and Therapeutic.

Descriptive Items.—The 301 descriptive items could be further sorted into five "syndromes" which accounted for 260 of them. The largest "syndrome" accounting for

over half the descriptive items, was composed of items describing the conventional "madman" who had difficulty in thinking logically (46 items), was unpredictable in behaviour (58 items), was withdrawn (24 items), and was paranoid (21 items) or suffered from other delusions (10 items). The other "syndromes" were depression (e.g., "morose," "hopeless," etc., 33 items), anxiety (e.g., "worries unduly," 34 items), social maladjustment (e.g., "can't mix," 27 items), and socially deviant behaviour (e.g., "antisocial," "criminal," 7 items).

Aetiological items.—The 154 aetiological items could be divided into 12% "organic" (e.g., "brain diseased or damaged"), 9% "constitutional" (e.g., "inherited," "not strong enough"), and 79% "environmental." The latter could be subdivided into general (e.g., "due to worry, circumstances of life," etc.) and more specific, such as "due to financial difficulty," etc. Very few people spontaneously remarked that mental illness was due to treatment as a child or connected it with personality development.

Therapeutic Items.—These were 117 items dealing chiefly with the need of the mentally ill person for treatment. Sixty-three items were concerned with unspecified "psychological treatment (good will, kindness, etc.). Seventeen specified rest or psychotherapy. Institutionalization and supervision were suggested in 20 items, and one of the physical treatments in 7.

Minority views.—Certain responses were not as much in evidence as might perhaps have been expected. Moral considerations were introduced in only two answers, and only six mentioned "unnatural cravings." Only one person mentioned malingering. Nineteen wrote about fear or horror of the mentally ill; 11 of them described this in themselves, 8 of them in other people, adding that it was unjustified.

To summarize, in these spontaneous answers 167 people—thought to be representative of the viewing public of Greater London—indicated what the words "a person who is mentally ill" meant to them. They seemed to think primarily of the traditional "madman," who could not think logically and was unpredictable, deluded, and withdrawn. Depressive, neurotic, and personality disorders were much less frequently mentioned. Aetiology was conceived mainly in terms of general or specific life stresses beginning in the recent past, with little mention of physical or hereditary causation. Therapy, similarly, was thought to consist of unspecific measures such as rest and kindness; the nature of psychotherapy was almost certainly not understood, and physical treatments were hardly mentioned.

II. Letters Written in Response to the "Hurt Mind" Programmes

An examination of the 1,267 letters written to the B.B.C. by viewers of this series provided some indication of the topics about which patients and their relatives expressed concern. Less than half of these letters complied with the invitation to submit questions which might be answered in a final programme; many of them consisted partly, or entirely, in an unburdening of the writer's own experiences and emotions. Several writers expressed their thanks for the evidence given by these programmes that *someone* was interested in their problems, and appeared to regard the act of writing to the B.B.C. as being in itself helpful to them. As might be expected, quite a number of the letters (approximately 20%) were written by persons who were themselves suffering from some form of mental disorder, but in only six instances were the contents of the letters dictated exclusively by delusions arising from the illness itself.

Of the total, 730 were from women, 372 from men: in 165 cases the sex of the writer was not indicated. This 2/1 sex ratio was shown in every topic studied in the content-analysis except three. The inequality was much less marked in letters concerning organic complaints (stroke, tinnitus etc.) and in two instances (questions about legal

formalities and about rehabilitation after mental illness) the men outnumbered the women.

In all, 1,842 topics were identified in the analysis. These could be categorized under the following main headings.

Requests for Further Information (mentioned in 526 letters)

This category includes all those letters which complied with the broadcast invitation to submit questions which could be answered on the air. The majority asked for more facts (and in some cases expressed disagreement) about matters touched on in the early programmes; some asked for the titles of good books on psychiatry. *Heredity* was the subject of surprisingly few inquiries (17 in all). Other forms of aetiology were mentioned in 23 letters, of which 13 discussed environmental influences and only 7 implied a belief in organic causes. Three writers asked if there is any foundation for popular beliefs about the influence of the moon. Only two persons explicitly asked about the relationship between neurosis and insanity. Five letters, all written by women, requested more discussion of the bearing of religion on mental illness.

Requests for Advice About Treatment (554 letters)

Many letters contained requests for help in dealing with a current illness of the writer or of someone in his or her household. Some of these described problems of such urgency that the producer of the television series passed 314 of them on to the National Association for Mental Health for their immediate attention.

It was possible in 91% of these letters to make a fairly confident guess at the diagnosis of the conditions described. Cases of neurotic illness (including character disorders and psychopathy) were described most frequently (202 letters), psychoses somewhat less (175), and mental illnesses with an organic basis considerably less often (128). These overall ratios were, however, very different when one contrasted letters describing the writer's own case with those describing illness in other people. In the former letters neuroses predominated, whereas in the latter cases of psychosis and organic illness were each twice as common as neuroses. It appears from this analysis that, whereas neurotic patients are readily able to express the need they feel for treatment, it is the relatives of psychotic and organically ill patients who are more likely to seek help on their behalf. It can be assumed that neurotic patients are more likely to have insight into their conditions: but these letters give the additional piece of information that in relatively few instances were correspondents concerned about neurotic illness in other members of the family.

In addition to asking what can be done in general for their sick relatives, 55 correspondents wanted to know what they personally could do to help them. In 29 of these instances the patient had refused to accept treatment, or to see a doctor, thus intensifying the relative's feeling of responsibility. Two persons described suicide in near relatives and wondered in retrospect what they might have done to avert this.

Unorthodox Methods of Treatment (21 letters)

Some of the letters received were concerned to impart information rather than to ask for it. This was particularly true of the writers who advocated unusual lines of treatment, such as biotherapy, scientology, "abntranosis," and "Dr. Croften's virus injections." The only one of such treatments which received support from more than one correspondent was *spiritualism*: 14 letters argued vehemently in favour of the healing powers of mediums and clairvoyants, three of the writers going on to explain that mental illnesses could most fruitfully be treated by exorcism.

Treatment in the Community (72 letters)

Concern about the presence of a mental patient in the household was often expressed. One woman wrote: "Surely the passage from skilled hands to total incompre-

hension from the family is a strain on the patient." Others dwelt upon the distress experienced by other members of the patient's family: "It is worse for the relatives of sick people, they have to face reality and cannot retire into the 'other world'." A woman whose husband has epileptic fits described herself as living "in awful perpetual dread of a seizure"; another with a severely disturbed epileptic child wrote, "She is ruining my health." One mother complained of her schizophrenic daughter: "She behaves just like a naughty child"; and another, in despair at her son's seemingly intractable psychosis, comes to the conclusion: "I feel that it would be more humane to put him to sleep, out of his misery."

In the great majority of cases, however, the relatives' concern was focused upon the patient's welfare after he or she had left mental hospital: and of those who raised the topic of treatment, no fewer than 39 (54%) said there is not enough aftercare provision. They also criticized treatment at psychiatric out-patient clinics, with comments such as: "One has a long wait in the out-patient department, and then a very cursory interview," or the recurrent complaint: "The psychiatrist just gave me pills which doped me." Individual writers made positive suggestions for extending the work of ex-patients' clubs and of occupation centres. One woman suggested: "Wouldn't it be better for patients to stay at work, living in a night hospital or a hostel if necessary?" Several writers made the point that the benefits of recovery in hospital could be lost if the patient were not helped to find suitable employment: six of these described instances where the ex-patient encountered the additional obstacle of prejudice instead of help in seeking work.

Stigma of Mental Illness (56 letters)

Patients and their relatives wrote with feeling about popular prejudice against those who have been mentally ill. Thus one woman, whose husband had suffered a depressive illness and thereafter could not find work, wrote: "The stigma of mental trouble is most damaging, and I begin to wonder if a man who has been to prison for some crime is certainly no worse off." A husband whose wife was severely depressed believed that her condition was aggravated by the attitude of their neighbours, who "said she was not safe to be with as she was a mental case." An ex-patient complained: "People make you feel you are not safe to be around." The parent of a mentally defective child pointed out that in his opinion this prejudice is apparent in the terminology of the law relating to mental defect. He wrote: "Mental defective is itself used almost as a term of abuse. Also 'on licence' and 'absconding' are terms suggesting a criminal aspect."

Three letters cited cases where members of the family themselves showed an unhelpful attitude towards a convalescent mental patient. It was implied that they should have known better; this implication was also evident in some bitter criticisms of the attitude of the patients' general practitioners.

General Practitioners (96 letters)

The practitioners' attitude to psychiatric illness, and their seeming powerlessness to help, were emphasized by both relatives and patients (but especially the latter). Doctors were accused of having no time for this type of patient, either literally or figuratively: "Doctors are always in a rush, haven't time to bother with you. Write you a prescription and say—Sorry, but it's not physical, it's yourself." "The doctor who I am under gives me sleeping-tablets; says he can do nothing else." "My doctor, who is a busy man, just gives me nerve tonics." "Our doctor hasn't much practice or understanding of this kind of thing: my husband has had thousands of tranquillizers and takes sleeping-tablets every night."

A woman patient wrote: "I have been to my doctor, but he just keeps giving me pills—they are too busy to talk"; and another complained that her doctor "always puts me off, tells me I must help myself, and gives me pills" (chlorpromazine). A man wrote: "Works doctors

do not understand about psychiatric illness"; and another: "I could go to my G.P., but what would be the use, as he does not know anything about this kind of illness?"

There is therefore among those who sent in letters to the B.B.C. a widespread opinion that general practitioners prescribe too many sedatives, and are disinclined or unable to give psychiatric patients the amount or type of attention which the latter think they need. In some cases patients said they were afraid to consult their doctors—for example, "A very harassed doctor gave me a brusque interview. He was quite scornful, told me to get a man"; and another wrote that she was reluctant to mention her symptoms to her G.P. again "in case I get another rebuff." Yet another wrote plaintively: "My doctor tells me I have got to overcome this myself, and I just do not seem able to do it."

Many writers, while complaining of their doctor's inability to help them, expressed gratitude for his attentions in other illnesses and sympathized with his heavy burden of work; but expressed the belief that most doctors neither understood nor sympathized with mental illness. Three writers urged that more attention should be given to teaching psychological medicine to doctors in training. On the other hand, a general practitioner wrote that in his opinion a great many minor neuroses respond to a brisk admonition to "pull yourself together."

Complaints About Hospitals (154 letters)

The large number of these letters implied considerable public dissatisfaction with the present state of the mental health services. Here the content of the first three television broadcasts especially provoked viewers' comments. The designers of the programme were anxious to put across a positive and optimistic picture of the work of mental hospitals and clinics; but as a result many people wrote to say that their experience had been very different. Surprisingly few letters came from patients currently in mental hospital, perhaps because it is in only a few institutions that patients are permitted to watch television programmes later than 10 p.m. (as were all of this series). In this category letters from relatives or friends were much more numerous than those from present or former patients (78% as against 22%).

The principal grounds for complaint were the lack of amenities in patients' surroundings and in their dress. Six writers laid particular stress on locked doors, which, as one put it, make the hospital "grim and prison-like." Seven letters made especial complaint of patients being left in idleness. One writer stressed both of these points: "Lots of mothers think the same as me; they should not be locked up. They will never get better like that, to sit about all day long watching each other. . . . Will you please take the matter up, about locking the patients in because they are afraid they might run away."

There were several complaints about overcrowding and about the mixing together of patients of widely different ages and degrees of severity of illness. Five letters mentioned brutal or harshly inconsiderate treatment by nurses. Another recurrent theme was the failure of doctors to give relatives the information they sought about patients in hospital. A patient's daughter paid a backhand compliment when she wrote: "My experience with the medical superintendent leads me to suppose that the one interviewed by Christopher Mayhew last night is a rarity."

Among the nine letters about institutions for mental defectives, four contained complaints about difficulties and delays in getting patients admitted, and three complained even more bitterly about obstruction of their efforts to have their relatives discharged.

In Praise of Mental Hospitals (24 letters)

After so much adverse criticism, it was a relief to find that there were a few writers who spoke with appreciation of hospitals and their staffs. One woman described the harrowing experience of trying to cope with her acutely

paranoid husband for some days before his admission to hospital: "I never want to live through that again . . . thank God there are such places." Only one person, a mother, spontaneously praised a mental deficiency institution; she said that her mongol boy was doing very well in "a splendid home where they work wonders."

Offers of Help for the Mentally Ill (26 letters)

Two writers proposed that volunteers should be invited to "adopt" and take a personal interest in neglected patients. Three others offered forthwith to entertain such patients in their homes. Two writers sent donations for mental health work, and four others described ways in which they were already befriending hospital patients; the remainder expressed their readiness to help if someone would advise them how they could best do so.

Questions About Formal Procedure (36 letters)

These letters were very varied in content, the only recurrent theme being requests for guidance on how to bring about the discharge of certified relatives (mentioned explicitly in six letters, and implied in a number of others). The remainder concerned questions of property and civil rights of the mentally ill. Two men wrote questioning the competence of the ordinary medical practitioner to sign certificates of unsoundness of mind; on the other hand, a woman J. P. and another correspondent wrote in favour of the fairness of the present certification procedure.

Organic Conditions (30 letters)

A number of correspondents wrote about conditions of medical rather than psychiatric concern, although the after-effects of a stroke (mentioned in 10 letters) may often include some mental impairment. Conditions such as myasthenia gravis, myopathy, tinnitus, and chorea had evidently been described to patients as disorders of the nervous system, and were misinterpreted as instances of "nerves." In contrast, two other letters (included in the first category above) were from relatives of melancholic patients who asked if it were true that in such cases "the depression nerve" is particularly affected.

Maternal Deprivation (7 letters)

In view of the widespread interest and discussion among mental-health workers of Dr. Bowlby's contentions about the lasting ill-effects of maternal deprivation in early childhood, all references to this subject were separately noted. It is evident, however, that this controversy does not appear to have made much impression upon the television-viewing public. Among those who expressed concern about the possible harmful effects of separation were a mother and a father who sought guidance about whether they should send their children (age 5 and 12) to an epileptic colony and to a residential school for blind children, respectively.

Miscellaneous (217 letters)

These letters ranged over a wide variety of topics, including euthanasia, the efficacy of prayer, the need for more pay for mental nurses, the law on divorce, and the question of suicide. In this category were included the few frankly psychotic letters, and several from less-disturbed patients who described their sense of isolation and their difficulty in communicating their feelings. A depressed married woman wrote: "Every time I look at my local newspaper I am shown the easy way. Should the Press print all the suicides? It cannot help the unbalanced." Another said: "The doctors on the T.V. programme all made it sound so easy to get well," and a third, still more depressed, exposed: "Why don't doctors tell the truth; there is no cure, only a bullet through the brain." Included in this miscellany were five letters protesting against the rather series of programmes, 12 complaining about the rather horrific faces which introduced the first broadcast, and

three expressions of thanks to the organizers of the programmes for directing public interest and sympathy towards this problem.

Discussion

The term "mental illness" is used by psychiatrists to cover a wide range of conditions, from frank psychoses to neuroses and minor personality disorders. The American studies have shown that in general it is the more severe disturbances which are popularly classed under this heading: milder emotional abnormalities are regarded as closely akin to everyday behaviour. The first part of the present analysis confirms this tendency in the London sample: for them, too, "mental illness" has become the accepted euphemism for insanity, whereas the milder forms of neurosis have not yet been generally recognized as illness.

This indifference to neurotic illness is not shared by the sufferers themselves, as was shown by the letters to the B.B.C. Such patients, and their relatives, strongly deplored the seeming reluctance of other members of the public, and especially of doctors, to treat them with the consideration and the specialized attention which they felt they needed. Here the limitations of this particular self-selected sample must be borne in mind. Those who wrote to the B.B.C. were moved to do so, in many cases, by pressing current needs, or by a lingering resentment against real or imagined mistreatment; this may account for the volume of criticisms against the doctors and hospitals. Psychiatrists by no means escaped criticism either, in spite of (or perhaps because of) the fact that the programmes were given a decidedly optimistic bias.

There is inevitably an uncontrolled bias in these samples, more especially in the case of the letters to the B.B.C.; yet it may be pointed out that social investigations, whether of sexual behaviour or of occupational status, have proved rewarding even though the populations on which they were based did not conform to rigorous principles of selection. The data revealed by this type of sociological serendipity can suggest fruitful topics for systematic inquiry. For example, it is noteworthy that so many correspondents express misgivings about the present facilities for the recognition and treatment of mental disorders. Nor were all the criticisms couched in negative terms; there were many constructive suggestions about increasing doctors' instruction in psychological medicine, and improving aftercare and rehabilitation services. In view of the recent Royal Commission's stress for an increase in "community care" it is interesting to find this indication, tenuous though it may be, of a reciprocal public readiness for such measures. It is probably relevant that the most popular item in all responses to the question asked at Broadcasting House was an expression of good will towards the mentally afflicted.

Mental illness is a disquieting subject, and one which is most feared when least is known about it. This investigation has suggested that in some quarters there still exists a good deal of disquiet and lack of information; and this in turn suggests the desirability for continuing efforts of health education in this field.

We thank Mrs. Adams, Dr. W. A. Belson, and Mr. Miller-Jones, of the B.B.C., and Miss Appleby and Miss Addis, of the National Association for Mental Health, for their co-operation in this inquiry.

Reviews

GRAY'S ANATOMY

Gray's Anatomy, Descriptive and Applied. Edited by T. B. Johnston, C.B.E., M.D., D. V. Davies, M.A.(Cantab.), M.B., B.S., and F. Davies, M.D., D.Sc.(Lond.), F.R.C.S. Thirty-second edition. (Pp. 1,604+xxiii; illustrated. 126s.) London: Longmans, Green and Co. 1958.

Textbooks, like human beings, seldom live for a hundred years. When they do, as in the case of *Gray's Anatomy*, it is because the original author hit on something which was urgently needed, and (quite as important) the successive editors kept well in view the original purpose and faithfully adhered to it. In the preface to the first edition (penned in August, 1858) Henry Gray clearly stated his purpose, which was "intended to furnish the student and practitioner with an accurate view of the anatomy of the human body, and more especially the application of the same to practical surgery." With that intent he made many dissections, and his friend Vandyke Carter sketched several hundred of them for insertion in the new book. Gray told his friend Timothy Holmes that he would have liked to include more strictly scientific matter, but he hoped to do so in a later edition. When the book was published it was welcomed by the *British Medical Journal* and the *Lancet*, but was severely, and unfairly, reviewed in the *Medical Times and Gazette*. The author was openly accused of plagiarism from Quain and Sharpey's book, and we think a careful reading of the long review gives a clue to the anonymous person who wrote it. It did the book no harm, and a second edition was called for within two years.

Unfortunately Henry Gray died in 1861, but his foundling was adopted by his friend Timothy Holmes, who inserted a long scientific introduction on general anatomy and histology which has remained a valuable feature of the work ever since. After Holmes had seen the book through seven editions it was taken over successively and successfully by Mr. Pickering Pick, Professors R. Howden, T. B. Johnston, and J. Whillis, and, in this latest edition, Professors D. V. Davies and F. Davies. Professor Johnston pays a warm and just tribute to the part played by the late Professor J. Whillis in helping to edit several editions, but the main credit for the present high standard attained must be given to Professor Johnston himself, who for nearly 30 years has efficiently supervised the revision of the work.

This centenary edition has been rejuvenated. Looking at its beautiful coloured pictures and excellent radiographs, noting the numerous references to recent researches and the surgical applications interspersed through the text, the reviewer feels a little envious of the modern student who has such a delightful and helpful companion as his guide. There is in this edition a very appropriate link with the original author, for Miss Fitton Jackson, a blood relative of Henry Gray, has contributed some excellent electron-micrographs. A happy thought also was the inclusion of photographs of five of the early editors, including Gray.

Henry Gray, Timothy Holmes, and Pickering Pick were all St. George's men, but the book is now a representative British work which has achieved international renown. Readers might like to know what this *Journal* thought of it a hundred years ago. In the *British Medical Journal* for November 13, 1858, the reviewer wrote: "We cannot avoid congratulating St. George's Hospital on the production of such a book by two of its own pupils—a book which must take its place as the Manual of Anatomy, Descriptive and Surgical." Not a bad prophecy.

ZACHARY COPE.

NATURE AND PURPOSE OF MEDICAL EDUCATION

For Future Doctors. By Alan Gregg, M.D. (Pp. 165+x. 26s.) Chicago: University of Chicago Press. London: Cambridge University Press. 1958.

In this book there are eleven essays by the late Alan Gregg, of the Rockefeller Foundation. They are delightfully written and are a pleasure to read. They offer a distillate

of the wisdom of a most able man who had made a wider study of medical education than any other in recent times. There is in them no mention of curricula, teaching-aids, schemes, or projects. Instead they state clearly the nature and purpose of medical education, and therefore they are of great value.

This is an era in which, not least in England, the medical profession faces the most serious danger possible—that of forgetting that it is a profession and by its own default ceasing to be one. Many join it now who have no experience or inherited awareness of professional life, and can acquire only those standards and values which they find in medical school and in practice. Intellectual honesty is hard to teach, and personal integrity can be shown only by example. Both can easily be made to bow before expediency, and when expediency is called realism then inspiration and creativeness are called idealism and are killed by kind ridicule. In these essays, written with the authority of one who knew most of the world's medical schools, Dr. Gregg rebuts this subtle propaganda and leaves no doubt that in reality we will lose all if we do not follow ideals. He quotes the words of Paul Valéry: "You must live as you think; if not, sooner or later you'll end by thinking as you have lived."

This book should be read by all future doctors. They will find in it a wealth of clear practical advice on two problems—what should be their aim and how they can achieve it. They cannot but benefit from the dreadful warning of "Preservéd Jones," who as a young man, in an age of bewildering increase in knowledge and fierce competition, was by his ambition to succeed led into dedicating himself to a narrow specialty. Now at 66, he is sadly complete, and "from his deliberate ignorance he cannot impart wisdom, or from his embitterment, serenity."

It is equally important, however, that all who teach should read, and read again, these essays by a man who saw so clearly the present predicament of the university—which must at the same time supply "stability of purpose and effort" and yet "be promptly and delicately responsive to changes in the environment and even changes in objectives." There are few who will not have to admit to suffering just a little from the "C.I.P." syndrome, the disease which can so easily affect those who belong to a "good" school of medicine: Complacency, Ingratitude, and Parochialism. There can be none who will not benefit from Dr. Gregg's words to the students of Texas: "He teaches best who shows his students how to learn: not what to think in 1953, but how to think and how to learn to think in that long stretch of days awaiting you till, let us say, the year 2000."

JOHN ELLIS.

THE LANGUAGE OF MEDICINE

The Story Behind the Word: Some Interesting Origins of Medical Terms. By Harry Wain, A.A., B.S.M., M.D., M.S.P.H. (Pp. 342+vi. 63s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1958.

As medicine becomes more and more technological any attempt to bring out its humanistic aspect deserves the warmest welcome. In this book the author has brought together a mass of interesting information not readily found elsewhere. He gives the origin and meaning of medical and allied scientific terms, the names of diseases, symptoms, signs, drugs, and instruments, with short biographies of their discoverers and inventors. He also includes popular terms such as "clap" (gonorrhoea) and "court plaster." Perhaps the greatest merit of the book is that it gives not only the changes in meaning which terms have undergone through the centuries but also the date of the adoption of the modern meaning and the name of the person responsible where this is known. So far as one can tell, the information is, in general, correct. On Lettsom, however, the author goes badly astray, describing him as "a Virgin Island physician who wrote an original account of alcoholism and gave an original description of alcoholic multiple neuritis."

Unfortunately the book is made unnecessarily bulky in several ways. It is written in full English instead of telegraphically, and no use is made of abbreviations such as *L.* for "Latin." Almost every item begins with some such sentence as "This term is derived from . . ." or "This term comes into our medical vocabulary from . . ." There are, moreover, a great many words, such as "education" and "eliminate," which are adequately dealt with in ordinary dictionaries. There is, for instance, a ponderous explanation of "visit." A worse fault is the inexplicable inclusion of words which have nothing to do with medicine—for example, "acrobat," "budget," "grass-widow," "Hobson's choice," "Portland cement," "daddy," and "ha-ha." These excrescences not only add to the size and cost, but also blur the author's admirable purpose of describing "the imagination and romance behind the language of medicine." The book could, without loss, be reduced to half its size. As it stands, it is far beyond the pocket of nurses and students. It should, however, be in every library, and teachers who wish to add human interest to their lectures would be well advised to use it.

FRANGCON ROBERTS.

EDUCATIONAL VALUE OF EXAMINATIONS

Goepp's Medical State Board Questions and Answers. By Harrison F. Flippin, M.D. Ninth edition. (Pp. 569+xi. 56s.) Philadelphia and London: W. B. Saunders Company. 1957.

This book, although new to me, was first published in 1908, and it is now in its ninth edition. Its 500 pages cover eleven medical subjects, including anatomy and physiology, and it contains answers to several thousand questions collected, one assumes, from the U.S. State Board examinations. The original author, the late Max Goepp, presumably approved the natural desire of students to pass examinations, and intended not only to save them the trouble of looking up the old examination papers but in doing so to provide them with much essential information. The book can then be used to discover how far written examinations can themselves contribute to the education of the student. Although these questions are for the most part unexceptionable examination specimens, such as the part unexceptionable examination specimens, such as the diagnosis of ruptured uterus or of posterior inferior cerebellar artery thrombosis, some questions, such as the treatment of the common cold (allotted 500 words) or of histamine headache, are more likely to educate the thoughtful examiner than to encourage rational thinking in the examinee. Since the questions chosen are mainly those requiring factual answers, demanding at the most a capacity for grouping remembered facts (answers of "the things on the bed, things in the bed, and things under the bed" variety), it may be that the candidate's experience and reasoning designed to test the candidate's experience and reasoning power.

The book has many merits. It is well printed and easy to read, and because it has been published so many times it is, in general, accurate and comprehensive in its information. Since many subjects are dealt with in one volume, it is possible for the student to refer easily to another section to resolve a doubt or to correlate facts—to look up in the anatomical section, for example, the situation of the restiform bodies and the vestibular nuclei when reading of posterior inferior cerebellar thrombosis, or to refer to the account of the phosphatases in the biochemical chapter when thinking about diseases of bone or liver. Although the book has a remarkable amount of information, it contains less than the cramming textbooks devoted to single subjects: much is omitted and much is presented in a form unsuitable for students. It is more authoritarian and dogmatic in tone than are modern textbooks; facts are stated without references, and hypotheses are advanced as facts without giving the evidence on which the theories are based. For example, it is stated that fat children are sexually retarded (itself unestablished) because the gonadal hormones are fat-soluble and are stored in the excess body fat—an ingenious but non-proven hypothesis; and the

long-held theory that gynaecomastia in liver disease is associated with an excess of circulating oestrogen is said to be supported by an increased output of oestrogen in the urine—a finding by no means universally accepted. The point here is not only that the student has been misled, but that an opportunity has been lost of allowing him to come to a conclusion as to the validity of a hypothesis by the presentation of the evidence.

The faults of the book are in some measure the faults of medical education and of the examination system. They can be illustrated by the frequent use of the word "significance" in these questions—for example, "What is the significance of the blood cholesterol?" (p. 235). The word "significance" is unqualified, and at its worst, therefore, it might denote an "examination significance" requiring a list of disorders in which the blood cholesterol is plus or minus (as supplied in the answer); at the same level it might imply the "retrospective diagnostic significance" of an unsuspected deviation of the blood cholesterol not suggested by the clinical findings; at a slightly higher level the "diagnostic significance" of an abnormal blood cholesterol waiting to be fitted into an already determined clinical pattern; and finally it should comprehend the only true meaning of "significance" as applied to the level of the blood cholesterol—the pathogenesis of a disturbance of cholesterol metabolism. And how much do we know of that?

It is not, then, surprising that a book of this sort should fail to teach medicine at a high level, for the authors have set their sights lower than this. Their objective is to assist the students to pass examinations. Such cramming textbooks are educationally damned for one reason alone—that knowledge hastily acquired is by most brains rapidly forgotten. This book can be unreservedly recommended only to the unfortunate emigrant Englishman who, having successfully emerged from the fiery trials staged in Lincoln's Inn Fields or Pall Mall East, is nevertheless compelled to face the State Board's qualifying examination.

D. V. HUBBLE.

The Student-Physician is a series of studies in the sociology of medical education, edited by R. K. Merton, G. Reader, and Patricia L. Kendall (pp. 360; Harvard University Press, 1957). It attempts to answer such questions as why students decide to study medicine and by whom they are influenced in making their decisions; when and why they decide to specialize; the attitude of students towards their future careers, and when and how they begin to think of themselves as doctors. The types of patients preferred by various kinds of students are also examined, and two papers are included giving experiences with the Cornell Comprehensive Care and Teaching Program, in which students serve as "family physician" to a particular patient and, if possible, to the patient's family as well. *The Student-Physician* is available in this country from the Oxford University Press, price 40s.

Pica, by Marcia Cooper (pp. 114; Blackwell Scientific Publications, 1957; 27s. 6d.), is a comprehensive survey of the historical literature on the subject by the assistant professor of public health administration at Johns Hopkins University. The author has included reports of pica in animals and has considered its anthropological and psychological implications. She has also studied its incidence in 784 pre-school children, of whom 21.9% were found to have a record of pica. It is suggested that poor nutrition may be the underlying factor.

Natural Selection and Heredity, by P. M. Sheppard (pp. 212; Hutchinson and Co. Ltd., 18s.), deals with some recent ideas on the mechanism of evolution. Two chapters explaining the elementary principles of heredity are included. The author has not attempted a complete survey of the whole field of population genetics, which would have been impossible in a book of this size, but has treated in detail certain selected subjects which illustrate important principles.

The Atom and the Energy Revolution, a Penguin Special by Norman Lansdell (pp. 200; 2s. 6d.), is an explanation of the social and political implications of developments in this field, written for the general reader, for the business man who wishes to adapt himself to the new environment, and for the specialist in other fields. A chapter is included on radiation risks and insurance against them.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 6 1958

THE STUDENT LIFE IN GENERAL
PRACTICE

William Osler, in his valedictory address to students at McGill University in 1905, exhorted them to remember that the education in which they had engaged themselves was not a medical course, but a life course, for which the work of a few years under teachers was but a preparation. He recognized that some of his listeners were natural students, and for them there would be little difficulty in a continuing devotion to books and journals; while others were students of men, practical fellows who enjoyed the diversity of God's creatures. The danger for the first group was that they might become bookish, shy, diffident, impractical men whose knowledge was therefore not readily available to meet their patients' needs; and for the second that they would become practitioners busily immersed in routine labours which left them without either the time or the inclination for study. The great clinicians are those who, like Osler himself, we may now add, are both students of books and students of men.

The need for the continuing education of the general practitioner is certainly not less than it was fifty years ago. The opportunities for successful diagnosis and treatment which lie ready to be used by the resourceful and educated family doctor are immeasurably greater than they were in Osler's day. He gave, in this and other addresses, much the same advice to the perpetual student-doctor as can be found, fifty years later, in the Fourth Annual Report of the College of General Practitioners, 1956, and in the article by Dr. George Swift in this issue (p. 580). The paramount requirement in continuing education is for good doctoring itself—good history-taking and examination, and careful records. This requires method and self-discipline, and too many, both inside and outside hospital, have to admit that from time to time they fall short of their own standards. The education of the medical student in these matters steadily improves, and good habits deeply rooted in youth are not so easily lost. Further, a few journals must be regularly read, the local medical society enthusiastically supported, and the refresher course

annually attended. Osler favoured a long period of postgraduate study every five years—the quinquennial brain-dusting—but to-day this is hard to achieve, and for most doctors it would be less valuable than a week's refreshment and stimulus each year.

As the need for continuing education is increasing, so are the opportunities. The fees and expenses of practitioners attending postgraduate courses, up to twenty-two half-days a year, are now paid by the Ministry of Health. There is no doubt, too, that the domiciliary consultation scheme has done much, not only for the education of both general practitioner and consultant but also for their good relationships. Consultants must be gratified to see it publicly stated by general practitioners that they find these consultations of considerable educational value. The increasing access of family doctors to x-ray departments and to pathological laboratories has vastly improved their facilities for studying the advances in the diagnosis of disease. Again, the opportunity to teach medical students and to train assistants has notably stimulated self-education in some general practitioners.

Although good progress has been made in the first ten years of the National Health Service, much remains to be achieved. The objective is to make continuing education as easy as possible for the largest number of general practitioners. Elsewhere in this issue (p. 583) Drs. John and Valerie Graves describe the early results of an interesting and hopeful experiment by the Medical Recording Service of the College of General Practitioners to provide medical talks on tape or disk for the doctor who finds it difficult to get to refresher courses. Their intention is not that the isolated practitioner shall listen to these records in solitude, but that he will gather a few of his neighbours to form a small discussion group to debate the medical message. The College hopes eventually to be able to provide for its members an up-to-date course in any subject.

For other difficulties there must eventually be found varying solutions. The Ministry of Health can provide further help: for example, by paying locum fees for the doctor in a partnership who is attending a refresher course. Most partnerships are at full stretch during the holiday periods of the summer, and to ask them to cover additional absence for postgraduate courses is to demand too much. More leisure for study, higher capitation fees, and merit awards—these are subjects which will receive increasing discussion in the next few years. Heaven—in this case the Ministry of Health and the Treasury—must show itself ready to help those who are now so obviously helping themselves.

PHARMACOPOEIAS AND FORMULARIES

The prescribing doctor of to-day is not short of pharmacopoeias and formularies, to say nothing of the spate of literature from the pharmaceutical houses that he finds in his letter-box every morning. Two new editions of pharmacopoeias have recently appeared, Volume I of the *Extra Pharmacopoeia*¹ ("Martindale") and the *British Pharmacopoeia*.² Seventy-five years ago William Martindale in collaboration with Dr. Westcott produced the first edition of "*Martindale*," a small volume of 313 pages. Martindale was at one time a pharmacist at University College Hospital, London, and later the owner of a retail and manufacturing business in New Cavendish Street. The *Extra Pharmacopoeia* was an immediate success, and edition followed edition until it was finally produced under the direction of the Pharmaceutical Society with the help of a panel of experts. The latest edition, the 24th, which contains some 1,700 pages, is a very valuable reference book for both doctor and pharmacist. For the first time the titles of the monographs are in English and not pharmaceutical Latin, an innovation introduced by the British Pharmacopoeia Commission five years ago. Doses are expressed for the first time exclusively in the metric system, the Imperial equivalents being added only for those drugs that are often prescribed in this system. In *Martindale* one can find the physical and chemical properties, pharmacology, mode of action, dosage, uses, side-effects, antidotes, and literature references for every drug likely to be prescribed. Not only are old remedies described, but also the latest drugs, such as sulphamethoxypyridazine ("midicel," "lederkyn"). The wide coverage of the book can be judged from the index, which contains 20,000 references. It is remarkable how up to date *Martindale* is, and Dr. K. Capper, the editor, is to be congratulated for his share in its production. There are references to a large number of foreign pharmacopoeias and to almost every proprietary preparation available in this country. There are special sections on antibiotics, immunological products, and radio-active isotopes. In each successive edition of *Martindale* the proportion of space allotted to new therapeutic agents has increased, yet with remarkably few deletions of the older and traditional remedies. There are some who deprecate the inclusion of many of the latter, yet they are still prescribed: once a drug becomes established, it takes a long time for it to become obsolete. Undoubtedly *Martindale* is one of

¹ The *Extra Pharmacopoeia*, vol. I, 1958, the Pharmaceutical Press, London. Price £3 5s. net.
² The *British Pharmacopoeia*, 1958. Published for the General Medical Council by the Pharmaceutical Press, London. Price £3 3s. net.

the most useful reference books on drugs for both doctor and pharmacist.

The *British Pharmacopoeia*, which is published under the direction of the General Medical Council at intervals of five years, is more useful to the pharmacist than to the physician. The new edition, which came into force on September 1, is the ninth. The *B.P.* lays down standards of purity, methods of testing and identification, and the doses of the more important drugs. The doses given are not binding on prescribers, but are intended for general guidance and represent the average range of dosage suitable for adults. *B.P.* doses are a useful guide for the pharmacist in checking quantities prescribed. As in the new *Martindale*, doses are now given in the metric system and the titles of the monographs are no longer in pharmaceutical Latin, but in English. The *B.P.* is drawn up by the British Pharmacopoeia Commission, of which Professor Dunlop, of Edinburgh, is chairman. Approved names for new drugs are devised or selected by the Commission from time to time. The permission given in certain monographs for the addition of a suitable colouring agent to the coating of tablets is an innovation.

The *British Pharmaceutical Codex*, familiarly known as the *B.P.C.*, was originally produced in 1903 by the Council of the Pharmaceutical Society as a book of reference for those engaged in prescribing or dispensing medicines. The need for a book of standards for drugs and preparations not in the *B.P.* became increasingly apparent, and the provision of such standards has become an important function of the *B.P.C.* The inclusion of a drug in the *B.P.C.* is now regarded as an indication that it is of value, or is an established constituent of a useful preparation. The monographs give a description of the drug, its sources or preparation, physical properties, a critical summary of its pharmacological action and uses, dosage, conditions for storage, and the treatment of poisoning through overdosage. Like *Martindale*, the *B.P.C.* continues to be a reference book of the greatest value in the practice of medicine and pharmacy. Its object is to describe all new drugs which clinical evidence and experience have shown to be useful. A new edition is due to appear next year. The many new compounds produced by a very active pharmaceutical manufacturing industry will provide ample material from which to select drugs for the new edition. A valuable part of the *B.P.C.* is the formulary section, which gives details of the preparation of a number of prescriptions and tablets.

The *British National Formulary*, which is produced by the Joint Formulary Committee of the B.M.A. and

that of American medical schools. Finally, a student does not graduate M.D. until after a year of rotating internship, during which he also has to write a thesis.

Departments Visited

Because of the impending move into a permanent centre, the University has been reluctant to spend money on the erection of large temporary buildings. Equipment, however, is freely transportable; there is therefore the paradox of inconveniently small and overcrowded departments magnificently provided with the latest American equipment.

Both the Anatomy and Pathology Departments have great difficulty because of religious objections to the examination of the cadaver. Consequently, eight or more students may work on a single body for the whole year, and this number was once as high as 20. Nevertheless, the students I met appeared to have at least as thorough a knowledge of topography as any of my Oxford contemporaries. When the Department first started there were only brains to study; it is now the custom to start dissection with the C.N.S. as an example in anatomical method and always to refer back to it. There is unfortunately very little emphasis on surface or surgical anatomy. The Histological Laboratory is furnished entirely with round tables centrally lighted, seating eight students. This attractive system saves space and makes for easy demonstration.

Physiology and biochemistry are taught as separate "block" subjects, and lead easily into the pharmacology of the fourth year. The all-purpose changeable laboratory for these subjects is makeshift and clearly inadequate at present. The departments are extremely well equipped and actively engaged in research. While the lecture syllabus is very full, the practical course is still unfortunately based mainly on animal experiments, and there is no adequate course in *human* physiology. Staff difficulties are common; usually one man in six is out of the country on a research grant; and all personnel must do one month each year in the Army. These factors, coupled with occasional illness, contribute to periodic overloading of the teachers.

The Pathology Department is very modern: it has a room for pathological photomicrography and an excellent small departmental library. Students have to master about 400 slides, and appear to receive a very thorough training. Museum facilities, however, are still poor. The Department runs the biopsy (about 7,000 a year) and necropsy (about 300 a year) services of Hadassah; it also teaches medical and dental students, engages in research, and holds weekly clinico-pathological conferences and sessions with many special departments—for example, thoracic, paediatric, and neurological].

The present clinical school has found temporary accommodation in a large polyclinic building and a series of hospitals not designed for teaching, but tolerably near each other. The wards are small and crowded; a ward with 10 beds would in London have only six. Neurosurgery and cardiac surgery are performed in Jerusalem and Tel-Aviv. In one small shed in the grounds of the Beth Hadegeel Hospital were a ballistocardiograph, for which students are research subjects, and all the apparatus necessary for cardiac catheterization. This housing of difficult techniques in small sheds is a characteristic paradox of life in Israel to-day, but should be unusual within 10 years.

The selection of clinical material was quite excellent, comprising the whole range of London hospital medicine as well as infestations and infections seldom encountered there. All patients are very thoroughly investigated and students are expected to be absolutely *au fait* with their own four or five patients. Students are responsible for routine blood counts, urinalysis, and microscopy, and the students' notes are official and are consulted along with those of the intern. This system gives clinical clerks a more possessive attitude to their patients and allows students to feel that their views are important and that the hospital would be the worse off without their work.

Hadassah Social Medicine Centre at Beth Mazmil

The emphasis on a scientific and research attitude to medicine is so great that it sometimes surprised me that students seemed to know their patients so well. The new Social Medicine Centre should counteract the tendency to forget the individual patient within the welter of investigations. It is described in some detail because social medicine is paid so much lip-service in Britain while so little is done outside of special postgraduate units. This centre was set up by a South African and an English doctor who aimed to do first-class general practice which would be as good as the best in their own countries. Special emphasis had to be placed on the preventive approach and on research. The population to be cared for consists of about 5,000 people who are largely new immigrants and range from destitute Moroccans to Anglo-Saxon intellectuals. All these people have been recently rehoused in a new estate in the Beth Mazmil suburb of Jerusalem.

The Centre itself is financed by Hadassah and has just moved to ample and pleasant new buildings. The staff of the Centre includes six G.P.s, of whom three are usually away (Army or study leave or illness), eight to ten well-trained nurses, a psychiatrist, psychiatric social workers, and an anthropologist. An infant welfare clinic and a birth control clinic are run from the main building. This last was less popular when two of the doctors became pregnant! While the doctors must have the exclusion and treatment of organic disease as their first concern, they are always on the *qui vive* for disease of psychosomatic origin. Psychosomatic illness is extremely widespread in Israel, presumably because of the horrors of the background of many immigrants and the daily stress of life in a new and pioneering country. The Centre has resident nurses who are each responsible for about 300 families, and it is therefore able to tackle this type of disease quickly and easily.

At the moment, students go out for lecture-demonstrations. They are allocated families to follow, usually including at least one with a pregnant mother where they can later study neonatal growth. In one or two years' time, when the Centre is fully on its feet, students will each do about three weeks of full general practice under supervision from the Centre. They may also participate in the research projects that are run from the Centre.

New Centre: Future Plans.—With regard to Mount Scopus, Hadassah has cut its losses. It has already started to build an enormous new centre in Ein Karim, a western suburb of Jerusalem, to hold schools of medicine, dentistry, pharmacy, and nursing, a library, a polyclinic, and 550 teaching beds, to be expanded later to 900. This scheme should be finished by the end of 1958, and is already ahead of schedule. It will be the main postgraduate medical centre of Israel.

Topics in Medical Education

Student Selection

The current joke of the Medical School is that the Hebrew University must be the most antisemitic in the world. Only 60 students are selected from about 300 applicants, and the University is not anxious to train students other than Israeli citizens or foreign students who have definitely immigrated and are still under the age of 21. At first the Medical School accepted those who had done their preclinical work elsewhere, but now acceptance is for the first year only. Three years ago 30% of the students were women, now only 6%. Private practice in Israel is more difficult to obtain even than in England, and consequently women are as unlikely to lead a full professional life there as they are in England. There is, however, no strict quota system, and women who are academically very good will be accepted. Money is not a factor in student selection: the School disburses £1,50,000 (£10,000 sterling) in scholarships, mainly provided from outside, and each diploma costs the School about £3,000.

Assessment

Curricula

Hospital appointments are nearly always full-time, and even a very senior chief will have only about six hours a week for his private practice. This increased time in the teaching hospital and the other factors of familiarity with students make examinations largely a formality. The teacher usually knows more about his students than an examination can tell him. Formal records are kept and examinations are held, but most students know they will pass. One student felt that there was "no feeling of competition to put out another student" as at her American university, but she "had to work very hard to keep up." In the final examination there are no formal written papers, but the detailed differential diagnosis has to be written and discussed in the clinical examination. Objective-type papers are not used.

Clinical Curricula of Two Students Chosen at Random

5th Year—In-patients		6th Year—Out-patients	
Surgery	6 weeks	Internal medicine ..	4 weeks
Tuberculosis ..	3 ..	Gynaecology	3 ..
Preventive medicine ..	3 ..	Dermatology	3 ..
Internal medicine ..	12 ..	E.N.T.	3 ..

		More surgery and paediatrics	5 ..
		Social paediatrics (antenatal work)	1 week
		Holiday	2 weeks
		Final examination ..	1 week
			41 weeks

Comparison with the English Curriculum

Psychology is more emphasized and is taught earlier than in Britain. Parasitology is very important and is taught in detail. However, students will conduct only about eight deliveries themselves (the obstetrician delivers babies), and they have no undergraduate training in anaesthetics. Paediatrics is very much emphasized: Israel is a growing country with a lot of children, and the care of these is in any case a major national obsession. The system of two months' work *à choix*—in Jerusalem or elsewhere—is attractive: choices varied from extra neurology in Tel-Aviv to a month with the G.P. on a communal settlement or in Beer-sheba among the Bedouins. Time spent on preventive medicine includes trips to factories in Haifa and to restaurants and sewers locally; there are seminars on such diverse subjects as the social incidence of tuberculosis, prostitution, and coronary atheroma.

Integration

Integration, if not a nasty word, is certainly a thorny problem. All agree that more is needed, but nobody is sure of how it should be done. Attempts are frequently made: a paediatrician lectures on neonatal growth and takes students to his wards during the anatomy course, and there is an x-ray machine in the anatomy department. Neuro-anatomy and neurophysiology are taught together, and the teaching in histology is of a functional character. Physiology, biochemistry, and pharmacology will eventually be integrated, at least in practical work. There is also discussion of a projected bioclinical course to give more basic science in the last two years. Clinico-pathological and clinico-radiological conferences and weekly hospital staff meetings are popular. Dr. Prywes, however, does not believe in full clinical-preclinical integration; instead he is concerned to try to get surgeons into the anatomy department and more *doctors* in the preclinical departments in general. He thinks the best method of integration is to encourage a system where teachers have dual appointments in the medical school and in the hospital—and there is a slight tendency towards this.

sterling. The School is prepared to make loans to students. Parental background is not important, and there is obviously no problem about the sons of alumni.

The pre-entrance examination has eight papers—four in science and four in the humanities. A student may be examined in two scientific subjects or in one scientific subject and one other subject. After this examination a hundred students go forward for the interview. Here there are about six teachers, and the object is the same as in other schools. The sub-dean, Dr. Prywes, described his method of interview and explained why he always wanted to know about special interests and hobbies. This was not because they might be of importance in themselves, but in order to test the knowledge claimed and to enable him to judge "how far the student was honest with himself about his hobby and might therefore be expected to be honest about medicine." Round-table arguments among students with teachers watching were discarded because they were technically difficult to arrange and students were shy. There is no discussion, and each selector marks for "in," "in if places available," or "out." By comparing the students' academic results with the original opinions of each selector, it is hoped to obtain over the next few years a group of good student selectors—or, at any rate, good selectors of good examinees—without regard to position on the staff.

The attitude of the Hebrew University to its selections is unusual. If a student fails (failure rates are as low as 3%) it is regarded as the fault of the school that selected and taught that student. Laziness is very unpopular with the faculty, but nevertheless failure without obvious cause is regarded as a slur upon the whole educational procedure.

Atmosphere of Learning

In the conversation quoted at the beginning of this article, both the approachability of the professor and his interest in and enthusiasm for teaching itself are typical of Israel and would be much less generally encountered in Britain. The most exciting facet of Israel for the visitor from abroad—and for the Jew in particular—is the atmosphere of everyone working together to create a new country quickly. Something of the infectious "muck in together" enthusiasm of the country expresses itself in the Medical School. Staff want to teach and students want to learn, both because they are really interested in their subjects and also because they want to produce good doctors for their country. Consequently staff-student relationships are amazingly informal with very few exceptions, even though not quite on first-name terms.

In the new buildings, staff and students will sit together at meals. Any problem can be discussed easily with any teacher, even with the professors. This type of relationship means that the retinue of registrars and housemen and the unnecessary formality of many English chiefs' rounds can be dispensed with and that students can learn much faster in this atmosphere. Much more emphasis is placed on the bedside tutorial and on the weekly seminars where staff and students can sit comfortably and discuss any problem which may arise during the week about the condition and treatment of particular patients. Unfortunately, I did not speak enough Hebrew to benefit from attending one of these seminars, but students assure me that these are very lively, popular, and instructive two-way procedures.

The Israeli student is as old as his English contemporary, but there the similarity ends. Often he is married; he may have one or more destitute relations to assist in supporting; he will usually take a laboratory job—at any rate during his clinical years; and, above all these major differences, he is passionately interested in medicine. He arrives at the hospital at about 8 a.m. and he might not leave it until 12 hours later; he works extremely hard. It is, of course, a pity that he should have to take these jobs, but it is agreed that these paraclinical jobs supplement formal teaching. He is said to miss a lot of the fun of student life and to be the worse for the lack of it. If so, I did not notice it and I enjoyed his company.

The General Medical Council has virtually given a free hand to the medical schools to reorganize the curriculum, and while experimenting there can be little harm in trying methods used in other countries.

The time has come to realize that the clinical student is no longer a schoolchild but an adult at one of the most impressionable periods of life, and, while the majority of teachers appreciate this, there are still many people who believe that those on the very bottom rung of the ladder should be seen and heard only when spoken to. The transition from student to doctor should be almost imperceptible, not suddenly on obtaining some letters after one's name.

Nova et Vetera

GRAY'S ANATOMY THE FIRST HUNDRED YEARS

Biologically, survival for a hundred years is sufficiently rare to be regarded as a curiosity, but in the world of books there are creations so timeless as to be unaffected by a century more or less of human regard. *Gray's Anatomy*, which was first published on September 1, 1858, can by no stretch of the imagination be included among these immortals. In earlier times, when age lent authority to medical as well as theological doctrine, it was commonplace for students to be examined on texts almost as ancient as their own civilization. That the same work should have served so many generations of medical students in a century which has seen greater advances in medical knowledge than had the thousand which preceded it is so extraordinary a fact as to rank with the curiosities.

What is the reason for it? Has anatomy stood still while all else has been on the march? Or is it so little regarded that the same manual which instructed our great-grandfathers will serve for our sons? What is so special about this book, that, in an age and in a department of knowledge where the very latest information is eagerly sought, it should reach the solitary eminence among current textbooks of celebrating its centenary? The answer must be that, like other centenarians, it owes its survival to the intelligence and skill with which it has been treated, at critical times, by its medical attendants, in this case a succession of distinguished editors and gifted draughtsmen. They have amputated, excised, grafted, and injected to such effect that Gray himself would regard with amazement the prodigy which has grown from his own modest offspring, although a closer inspection would enable him to recognize its original features.

Henry Gray

The son of a Court Messenger, Henry Gray was born in 1827 and enrolled as a student at St. George's in 1845. Painstaking industry, rather than brilliance, won him an important prize from the Royal College of Surgeons in 1848, and at the age of 25 he was elected a Fellow of the Royal Society, a distinction less notable then than it is to-day. For a dissertation "On the structure and use of the spleen" he was in 1853 awarded the Astley Cooper prize of 300 guineas. He was, then, a young man of promise and some achievement—but not the greatest or even the most knowledgeable anatomist of his day—when he set out to provide the student, within the covers of a single volume, all that he needed to know of human anatomy in order to pass his examinations and to practise competently as physician or surgeon.

His duties as demonstrator and lecturer on anatomy at St. George's, and as curator of its museum, gave him the experience and material necessary for such a work. Within his own circle of friends and colleagues he was fortunate in

having a first-class draughtsman, Henry Vandyke Carter (1831-97),¹ who had also held the post of demonstrator of anatomy at St. George's, and an unusually skilled literary mentor, Timothy Holmes (1825-1907),² who was also a surgeon-anatomist. Gray's debt to his illustrator is plain for all to see, and the early success of the book has been attributed to the excellence of Carter's drawings. Of these there were 363 in a volume of 750 pages. The greater part of them were entirely original, but some were borrowed—with acknowledgment—from the works of Quain, Arnold, Breschet, Mascagni, and others, the black-and-white of the woodcuts being relieved by colour only in the sections on the blood vessels, where blue and red indicate veins and arteries. The order is similar to that of modern editions,

FIG. 1.—Henry Gray (1827-1861), from an original photograph taken by Henry Pollock. By courtesy of the Wellcome Historical Medical Museum.

but sections originally dealt with separately are now grouped together under the comprehensive headings of angiology, neurology, and splanchnology. Notable by their absence are the now familiar introductory sections on histology and embryology.

The publisher, John W. Parker, included many of the great Victorian authors in his list. He was printer to Cambridge University and is remembered for the introduction of the steam-press against considerable opposition, especially when it was employed in printing Bibles, a proceeding regarded as faintly sacrilegious. His imprint also appeared on the second edition in 1860, but in 1863 he retired and sold his business, with all his copyrights, to Longmans, whose name is found on the title-page of Gray's third edition in 1864.

Work must have begun on a second edition almost immediately, for it was published at the end of 1860 with a number of revisions and corrections by Gray and with 32 additional illustrations, 27 of them from new and original drawings by John Guise Westmacott (1811-84). This was the last edition for which Gray himself was responsible. In June, 1861, while attending a nephew suffering from small-pox, he contracted the disease and died within a week. He was 34.

Later Editors

It was fortunate for the future of Gray's book that his friend Timothy Holmes, who had just begun publication of his *System of Surgery*, agreed to take over the third edition, which was published by Longmans in January, 1864. Few changes were made at first, but for the fifth edition (1869) Holmes supplied an introductory section on general anatomy and development "so as to furnish the student with a very succinct, but it is hoped sufficient, introduction to Microscopic Anatomy." He also included a description of the ovum and structures characteristic of the foetal state, "a subject passed over in previous editions." As he thought it

FIG. 2.—The title-page of the first edition, from the copy in the Wellcome Historical Medical Library.

"useless to manufacture new drawings" to accompany this additional text, suitable illustrations were borrowed from Kölliker, Tedd, Bowman, and others. In subsequent editions, until the ninth (1880), the last which he edited, Holmes continued to pay particular attention to the section on histology, and additional illustrations were added from the Klein's *Handbook for the Physiological Laboratory* and the same author's *Atlas of Histology*. The section on visceral anatomy was also thoroughly revised with the aid of Professor Darling, of New York, and the account of the anatomy of the kidney was rewritten by E. J. Spitta.

Even when Holmes felt that it was time for him to hand over his task to another the link with Gray was still unbroken, for the new editor, Thomas Pickering Pick (1841-1919), was not only a St. George's man but had actually learnt his anatomy from Gray himself. Under his care the stately progression of editions continued unabated, each larger and more comprehensive than the one preceding. The tenth edition (1883) had some new drawings made from fresh dissections carried out at St. George's; the thirteenth (1893) drew on the resources of the Hunterian Museum of the Royal College of Surgeons and new dissections were

made there by Professor Pearson, who also helped in the preparation of the drawings, some of which were printed in colour. Pick retired in 1900, but he collaborated with his successor, Robert Howden (1856-1940), in preparing the 15th and 16th editions (1901, 1905). To judge by the glowing portrait of Howden, written by the late Professor Grey Turner when Howden died, he was a very different character from Pick. Howden, who was professor of anatomy at Durham University, "made the subject of anatomy of living and surpassing interest" to his students. Pick "was rapid and correct, but not very inspiring, for he followed the lines of *Gray's Anatomy* so closely that he was popularly reputed among the students to know that elaborate treatise by heart." Pick had introduced the use of rather unsatisfactory half-tone blocks into the illustrations. In the 16th edition (1905) a return was made to woodcuts and line drawing, ostensibly "to lighten the weight of the book," which now had 1,248 pages and 811 illustrations. In the course of his 25 years as editor of the *Anatomy* Howden carried out innumerable dissections for the purpose of new illustrations and constantly strove to keep the book up to date. According to Sir Thomas Oliver, "when he was about to bring out a fresh edition he had the artist for weeks by his side in the college, so careful was he about the minutest details." It was at Grey Turner's suggestion that a reminder of its original author was given to the reader in the 23rd edition (1926), the last which Howden edited, in the form of a brief biographical memoir and portrait of Gray.

It would take up too much space to name all those who have had a part in producing the various twentieth-century editions. The book has followed a parallel course in America, where one of its most important editors was W. W. Keen. When Professor T. B. Johnston, of Guy's Hospital Medical School (later assisted by Dr. J. Whillis), took over the editorship from Howden in 1930 the book was again drastically revised and partly rewritten, and the 24th edition of that year had grown to 1,466 pages and 1,301 illustrations, of which 607 were coloured. The Centenary Edition—the 32nd—which is noted elsewhere in this issue, must therefore be looked upon as the mature product of many minds and many hands. A close analysis would enable us to determine exactly how much of Gray is left in it, but it would be a pointless task. He was once the author of a book, but he might more truly be regarded as the founder of an institution.

"It has always seemed to me that the best of all ways to convey an idea is with chalk. Not only does the speaker get a doubling of the receptive channels—the visual added to the auditory—but the progressive adding of each element to the structure of the drawing drives home, piece by piece, a thing not quickly or completely grasped as a whole from a previously prepared, complete drawing. In teaching the medical student the primary requisite is to keep him awake; obviously you cannot teach anything to a sleeping man. Like the exhaust of the airplane the patter of words of a read paper is soporific. Chalk-talking arouses the drowsy. When a late-hour student seemed to be on the verge of succumbing, he could be brought back by speeding up the drawing or by changing to a correlated subject. For example, the sleepy student could not resist a chalk demonstration of tracheotomy, in which the patient, first shown as apparently dead of asphyxia, is changed by a few strokes to a smiling, grateful patient, and is quoted as saying, 'Thank you, Doctor Jackson.'" (From *The Life of Chevalier Jackson—An Autobiography*. Macmillan Company, New York, 1938.)

At present there is no quota for medical students in the University of Oxford: the preclinical entry is about 75 per year, of whom about 12 may be women. Some of the colleges have formed themselves into groups for the purpose of considering applicants to read medicine, and the following extracts from the *Oxford University Gazette*, June 13, explain the position: "University, Balliol, Trinity, St. John's and Jesus Colleges and St. Peter's Hall will act as a group

Even with the development of these new academic departments for teaching and research, and the provision of an increased number of teaching beds in the Radcliffe Infirmary, the university does not intend to increase the size of the clinical school, which will remain limited to an intake of 32 a year. The majority of the students are drawn from the preclinical departments of the university, but some are admitted from other universities. In the past all external students have read for the degree of their parent university. Most will continue to do so, but a university statute now makes it possible for selected students from other universities to apply to take the Oxford B.M. degree without having taken the preclinical course at Oxford or the Oxford B.A. Students from other universities in the United Kingdom and overseas who apply to read clinical medicine in Oxford and take the Oxford B.M. under the new regulations must have spent three years in the study of the preclinical sciences, have passed an examination equivalent to the first B.M. in anatomy and physiology, and have obtained an honours degree in the arts or sciences.

The aim of the university in limiting the number of clinical students is to ensure that each gets the maximum amount of personal instruction so that the scientific approach to the problems of medicine and the habit of independent thought, which is the hallmark of the honours course in physiology, can be fostered during the period of clinical study. The small size of the school makes it possible for each student to have a personal tutor and ensures that all have direct access to a large number of patients. Now that the pre-registration year has become part of the training of a medical student a further advantage that accrues from limiting the intake is that almost all who qualify from the United Oxford Hospitals can be sure of obtaining a pre-registration post in their own teaching hospital.

Cambridge

At the University of Cambridge the number of candidates wishing to study medicine continues to exceed the number of places available, and all college entries are subject to a university quota.

Two changes have been made in the regulations for the final M.B. examination. The first relates to the period of clinical instruction in midwifery and gynaecology. The regulations are amended so as to specify requirements of (a) six months' instead of three months' clinical training; (b) two months' instead of one month's residence in a maternity hospital; and (c) instruction in antenatal and post-natal care. Students who began their clinical training before October 1, 1956, however, will be allowed to proceed to the final M.B. examination on producing evidence satisfying the midwifery and gynaecology requirements previously in force.

The second change is designed to permit undergraduates who by the end of their second year's residence have obtained honours in the natural sciences tripos and have qualified in anatomy and physiology and who wish to undertake a course of non-medical study during the third year in Cambridge, to take the final M.B. examination at the same time as their contemporaries who devote three years to the tripos and qualifying examinations. The requirement that a candidate for either part of the final M.B. examination shall produce evidence of having completed five years of medical study has been amended to restrict the requirement to Part II only of that examination. The Cambridge medical student normally completes three of these five years as an undergraduate in residence, and on October 1 following graduation begins clinical studies at a recognized hospital. If, in the circumstances mentioned, the third year is devoted to non-medical study the student will begin hospital training with two years' medical study only to his credit, but will be allowed to count as part of his third year of medical study after graduation the period of three months during which he attends the long vacation course in elementary clinical methods. He will then be able to take Part I of the final M.B. (pathology and pharmacology) in the December of his third academical year at hospital and Part II (medicine, surgery, and midwifery and gynaecology) in the following June, if he begins hospital training in the July immediately following his qualification for the B.A. degree either in his clinical school or by taking the long vacation course in clinical methods in Cambridge.

TEACHING-HOSPITAL CENTRES IN ENGLAND AND WALES

Birmingham Medical School

The number of applicants wishing to enter the University of Birmingham Medical School greatly exceeds the number of places available, and requests for admission should be made by April of the preceding year for entry to both first- and second-year courses. Applicants in the United Kingdom are interviewed as soon as possible and told the result of the interview within a few days. There are 14 places available annually for first-year courses (students from the Colonies or Dominions are generally required to enter upon

first-year courses), and about 100 places per annum for men and women for second-year courses. Ten scholarships are available for selected students to spend an extra year to take the B.Sc. course in the honour school of either anatomical or physiological studies. Students from Oxford, Cambridge, and other universities are encouraged to study clinical subjects at Birmingham. Two interesting scholarships provide the opportunity of spending three months in residence in either East or West Africa, principally to gain experience in tropical medicine, although part of the time might be spent in some other clinical department. Advanced clinical students may spend some time with selected general practitioners, and a prize has recently been instituted as an award for an essay bearing on some topic of general practice.

The entire curriculum is under review, and an attempt is being made to integrate, so far as possible, the teaching provided by the several departments.

The library service within the medical school is an excellent one in that not only have students access to one of the largest collections of up-to-date medical literature in the provinces, but the resources of the whole university library are open to them. Sport at Birmingham is organized by students through the Guild of Undergraduates, and students may join, without further subscription, any of 30 clubs. Sailing and rowing excepted, all facilities lie within 400 yards of the medical school.

New Teaching Hospital for Sheffield

The recent laying, by Queen Elizabeth the Queen Mother, of the foundation stone of a new out-patient department for the United Sheffield Hospitals seems to indicate definite progress towards the ultimate provision of a complete new teaching hospital. New university building has not so far greatly affected the Sheffield Medical School, although a generous grant from the Rockefeller Trustees has furthered the activities of the department of microbiology. Assistance from the Sheffield Town Trustees has enabled the university to take a larger share in developing the department of psychiatry, while the building by the United Sheffield Hospitals of the new Whiteley Wood Clinic (an extension of the idea of a psychiatric wing within a general hospital) has also greatly assisted the department.

The discussions regarding the curriculum, referred to last year (*Journal*, September 7, 1957, p. 575), are expected to bear fruit next summer in the shape of considerable changes in the clinical part of the course. The arrangements for the various clerkships and dresserships will be modified, the orientation towards examinations and the timetable will be considerably altered, and two "elective periods" will be introduced. Partly in order to assist the students in the arrangement of their work during these periods, Dr. I. B. Sneddon has been nominated as director of clinical studies. A pilot experiment relating to the development of a tutorial scheme already shows much promise of success. Professor R. P. Jepson has resigned from the chair of surgery to go to Adelaide University; Professor W. Hobson from the chair of social and industrial medicine to take up a W.H.O. appointment in Copenhagen; and D. J. Pemberton from the same department on his appointment as professor of social medicine in Queen's University, Belfast. The future of the department of social and industrial medicine in Sheffield is now being considered by the university.

Liverpool's New Medical School

At Liverpool University the outstanding event of the year was the official opening of the new medical school by Queen Elizabeth the Queen Mother, an account of which was given in the *Journal* of May 17 (p. 1172). The new building houses the research laboratories of the departments of medicine, obstetrics and gynaecology, pathology, bacteriology, pharmacology and general therapeutics, and radiodiagnosis, six tutorial classrooms, three lecture theatres, two large class laboratories, museums, the dean's offices, a staff common

room, and a committee room. 91 new students were admitted to the M.B. course last October, and of these 42 entered the first year and 49 the second year. The number of applications for admission is slightly fewer than in previous years, but competition is still keen and a full complement of students will begin their studies this October. There have been no changes in the requirements for exemption from the first M.B., and passes at the advanced level in chemistry, physics, and biology (or botany and zoology) are still needed. The General Medical Council's new recommendations on the medical curriculum are receiving attention, but no changes have as yet been made.

A full-time readership in medicine has been established, and Dr. C. A. Clarke appointed to the post. Professor T. N. A. Jeffcoate is visiting Canada, U.S.A., and the West Indies as Sims-Black Commonwealth travelling professor in obstetrics and gynaecology. Professor R. M. Gordon, who has been a professor in the Liverpool School of Tropical Medicine since 1930, is retiring from the chair of entomology and parasitology after long and distinguished service, and Mr. A. McKie Reid from the post of lecturer-in-charge of the department of ophthalmology. Also, during the session Dr. Robert Coope, Mr. Hugh Reid, and Mr. John McGibbon have retired after long and devoted service as teachers in the clinical school.

Department of Psychiatry at Leeds

At the Leeds University new premises for the department of psychiatry were opened in January. They are in Hyde Terrace, adjacent to the department of biochemistry. Three large houses have been converted for the use of the department and provide administrative, library, research, and teaching accommodation, and also accommodation where patients can be seen. While it remains the long-term plan to provide this accommodation within the teaching hospital, in the meantime these new premises add greatly to the facilities available to the department. The building of the Martin Wing of the teaching hospital is well advanced and it is hoped that the full-time professorial units of medicine and surgery will be able to move into their new accommodation before the end of the coming session.

No major changes in the curriculum have been made during the last year, nor are any likely in the immediate future, though consideration is being given to entry requirements and the content of the premedical part of the course. There has been only a small reduction in the number of applications for entry, which continue to exceed the number of places available.

New Regulations at Manchester

The most important change is that new regulations have been introduced for the first M.B., Ch.B. examination. From October candidates who have passed in chemistry, physics, and biology (or zoology) at the advanced level of the G.C.E. will be entitled to exemption from the first M.B., Ch.B. examination and eligible for admission to second-year courses. Such candidates will be able to complete the full course for the degrees of M.B., Ch.B. in a minimum of five years.

A pilot scheme has been introduced to provide additional opportunities for students to obtain training and experience in general practice. With the help of the local Faculty of the College of General Practitioners, students have been attached to selected general practitioners, and the scheme has been very successful.

Residential Accommodation at Durham

At Durham University the extensions to the department of anatomy and to the animal house are nearing completion, and the additional accommodation which they will provide should be ready for occupation by the end of September. As part of the general college plan to provide more residential facilities for students it is hoped to start work next year on a new hall of residence for 225 male students, while in the near future conversion and additions to the present

buildings should provide accommodation for an additional 80 women students. King's College has also rented a large hostel from the Ministry of Pensions and National Insurance which, after renovations have been completed, should accommodate an additional 500 male students by next October. The hostel will be known as the Eustace Percy Hall, after the late Rector of King's College.

Once again the Medical Students' Council has been most active in representing the interests of medical students both in the college and on the British Medical Students' Association. Mr. Peter G. Wood has been elected president of the British Medical Students' Association. The Medical Athletic Union and the Medical Society completed a full programme of sporting events, visits, lectures, and social activities.

Bristol's Plans

The planning of the new medical school at Bristol University has been completed, and building is expected to start in the autumn. The number of applications for the undergraduate course in medicine has remained at the same high level as for the last several years. Major alterations are now taking place in the teaching hospital to improve the clinical facilities and accommodation for students. Some modifications in the medical curriculum have been introduced, mainly with the purpose of allowing a greater amount of voluntary attendance in lecture courses.

Welsh National School of Medicine

The school sustained last year a serious loss in the death of Lord Aberdare, its president for many years. The court of the University of Wales has elected Sir Clement Price Thomas to succeed him.

During the past year the details of the schedules of accommodation for the new teaching centre in Cardiff have been agreed with the Welsh Board of Health. It may be some time before building can start, but there is every hope that an architectural competition will soon be announced for a centre where educational and hospital accommodation is to be completely integrated. In the meantime the school is proceeding with the building of a dining hall and library, which will have the effect of improving amenities for students. Additional houses have also been acquired, so that hostel accommodation will be adequate for all those who desire it. The school authorities, like many others, are engaged in revising the curriculum, but, although it is not likely that this will be completed for some time, improvements are being made especially in the direction of correlating teaching in the different departments. The student health service of the University of Wales, which is administered by the medical school, is extending its activities, and it is hoped to provide more and better accommodation.

During the past year a careful review of the pre-registration appointments in the Welsh Region has been made, with a view to ensuring that times spent in them is a real extension of medical education, and for this the co-operation of the regional consultants is being enlisted. The school has received many visits from visiting societies, and the lectures in connexion with these have proved stimulating to both undergraduates and postgraduates. Invitations have also been received by several members of the staff to visit countries and universities abroad, which the school regards as a most valuable means of extending its influence and reputation.

SCOTTISH SCHOOLS

Edinburgh University

At the University of Edinburgh the past year has been one of continuing activity. The number of applicants for admission to the M.B., Ch.B. course this year remains high in relation to the number of places available. Those applying for admission for the course beginning in October, 1959, should submit their applications to the dean of the faculty by December 31. A limited number of undergraduate

bursaries and scholarships are available to students in the faculty of medicine for advanced courses of study—for example, an honours course of instruction for the B.Sc. degree.

Extensions at Glasgow

At Glasgow University plans are well advanced for the building which will house the new department of virology and also an extension to the genetics department. It is hoped that the new building will be available for occupation in two years' time. A start is expected to be made this year on a new unit for experimental surgery. The number of applications for admission to the medical school is very similar to that of last year. It is still in excess of the number of available places. The most important staff changes are the promotion of ordinances for the institution of chairs in orthopaedics and in infectious diseases. The junior teaching staff has been augmented by several additions in the lecturer grade.

Aberdeen University

At Aberdeen University the curriculum for the degrees of M.B., Ch.B. extends over six academic years. Courses in the premedical and preclinical subjects are given in departments located in Marischal College and in Old Aberdeen, which provide instruction for science as well as medical students. Laboratory and lecture courses in the three clinical years are conducted in the university buildings on the Foresterhill site, where the main hospitals are, and clinical instruction is given in all the hospitals in Aberdeen. The number of students for admission continues to tend to fall, but it is still above the number of places available. An increasing number of applications are coming from overseas students in various parts of the Commonwealth.

During the year a building to accommodate a special research department in clinical midwifery was completed and opened officially in April. It is staffed by the Medical Research Council, and its honorary director is the professor of midwifery. Plans have been prepared for a new medical physics building on the Foresterhill site, but work on it is unlikely to start until early next year.

A new medical ordinance promoted by the four Scottish universities has been approved. It permits certain candidates for admission to the medical faculty to sit the professional examination in physics, chemistry, and biology without attending university classes in these subjects. Each university can make regulations for this purpose, but so far the University of Aberdeen has not done so. They consider that the time has come to review as a whole the ordinances which govern medical education in the four Scottish universities. These were made as long ago as 1911 and are so restrictive in character that they interfere seriously with the prevailing mood of medical educationists in seeking experiment. It is proposed that a conference of the Scottish universities should be held early next term to consider the question of preparing new ordinances.

St. Andrews University

In the school of medicine of St. Andrews University instruction in the subjects of the clinical years of study is given in Dundee, while the premedical and preclinical subjects can be studied either at St. Andrews or at Dundee.

The annual intake of students to the faculty of medicine is limited to between 70 and 80 to ensure that the hospital facilities available are sufficient to allow of adequate clinical instruction being given to each undergraduate. The laboratory accommodation in both preclinical and clinical years has been recently extended and provides excellent facilities for students. There are at both centres excellent student residences which accommodate undergraduates from all or any of the faculties. Medical students in their early years are encouraged to reside in these, so that there is a width of contact among the undergraduates which is found to be of great educational value.

NORTHERN IRELAND

Queen's University, Belfast

The combined clinical course—a modified integrated curriculum—now enters upon its fifth year, and a committee has been sitting to review its results and to suggest modifications in the light of the new and more elastic recommendations of the General Medical Council. A new geriatric unit has been provided in one of the general teaching hospitals, and a new unit for the department of mental health in the same teaching hospital will be opened in the new year. The policy of attaching maternity students to general practitioners during part of their residential period has been most successful.

Professor Alan Stevenson has left to go to the Medical Research Council unit at Oxford and Professor J. Pemberton has been appointed to the vacant chair of social and preventive medicine. Dr. John Dundee, a Belfast graduate, has returned to head the new department of anaesthetics.

MEDICAL EDUCATION IN EIRE

Trinity College, Dublin

The entry of students has been restricted so that the numbers in the clinical years will probably not exceed 50 in future. The chairs of medicine and surgery are now full-time appointments. Clinical tutors in medicine and surgery have been appointed in the hospitals attended by school of physio students, under the direction of the clinical professors. Special arrangements for the teaching of paediatrics and for clerking in this specialty have been made jointly with the Rotunda and the National Children's Hospital. The professorial unit at the Rotunda Hospital has worked very satisfactorily during the past year.

The laboratories of anatomy, physiology, biochemistry, and pathology have undergone extensive alteration and reconstruction, with new equipment and increased facilities for research. Plans are being prepared for new accommodation for pharmacology. An extension of the chemistry building, now completed, provides greatly improved accommodation for premedical classes. Additional classes and demonstrations in pathology, bacteriology, and clinical biochemistry have been arranged in each of the hospitals; these are directed by the respective professors and carry on the systematic teaching of these three subjects up to the final academic year.

National University of Ireland

The constituent colleges of the National University of Ireland are those of Dublin, Cork, and Galway.

At *University College, Dublin*, the total entry to the first medical year is limited to 100 students, who are admitted on the results of the premedical examination. The maximum number of students admitted from outside Ireland is 20. Before a student may present for the M.B., B.Ch., B.A.O. degrees he must have passed the prescribed examinations having attended the necessary courses—that is, premedical year and five-year medical courses. These courses consist in lectures and practicals given at the college and attendance at clinics in recognized hospitals. In addition to the M.B., B.Ch., B.A.O. degrees there are a number of postgraduate degrees and diplomas, for some of which courses are held. Several new chairs have been established in the medical school for the coming session. There are now two full-time professors of surgery and of medicine. In addition, a chair of microbiology as applied to medicine and a chair of pharmacology have been established, and the appointed professors will have taken up their duties by October.

For some years *University College, Cork*, has restricted its entry to 36 medical students, only two of whom may be from overseas. Selection is made by the premedical examinations. The school has reverted to the six-term period of study in anatomy, physiology, and biochemistry in preparation for the second M.B. The introductory clinical course

has been abolished: instead, the department of physiology provides a course in clinical physiology in hospital during the last term; there is an introductory course in pharmacology; and the student receives instruction in elementary pathology, a question bearing on this subject being included in the professional examination in anatomy. The results of this approach to integration are being watched. Apart from obstetrical and specialist units, there are over 500 acute beds available for clinical study, which follows the lines customary elsewhere. The beds are distributed between three general teaching hospitals. Increasing attention is being given to research. Notable contributions have already been made by the departments of biochemistry, physiology, and anatomy. A gratifying addition to the resources of the department of anatomy has recently been made by the completion of two research laboratories, the cost of which was generously contributed by the Wellcome Trust.

At *University College, Galway*, the course for the degrees of M.B., B.Ch., B.A.O. covers six academic years. Courses in the premedical subjects are given in the college, and courses in the clinical subjects principally in the Regional Hospital, Galway. The latter is a new general hospital of about 500 beds, situated quite near the college. During the session just ended a new building for the hospital's departments of pathology and bacteriology has been completed and come into use, and the formal instruction of the medical students in pathology and bacteriology is now all carried out there. Clinical instruction is also given in the Western Chest Hospital, and in the Western Orthopaedic Hospital at Merlin Park, Galway. These are new hospitals with about 700 beds between them. Clinical instruction in psychiatry is given both in the Central Hospital, Galway, and in the Ballinasloe Mental Hospital. The summer term of the fourth medical year is spent in Dublin chiefly to enable students to reside in an obstetrical hospital for a period of two months. It is hoped that facilities for such residence will be provided in Galway in the near future. House appointments and registrarships are available for graduates in these hospitals.

Royal Colleges and the Apothecaries Hall

The *Royal College of Surgeons in Ireland* admits to the pre-registration classes approximately 100 students each year. The normal method of entrance is by competition in the preliminary examination, but a limited number of places are given to those with exceptional qualifications and to certain students selected through the Colonial Office.

The *Royal College of Physicians of Ireland* is an examining body for the M.R.C.P.I. In addition it forms with the *Royal College of Surgeons in Ireland* the Irish Conjoint Board which grants licences in medicine, surgery, and midwifery (L.R.C.P. and S.I., and L.M.).

The licentiatehip of the *Apothecaries Hall of Dublin* entitles to registration under the Medical Act, 1886. It enables the holder to practise pharmacy, as well as medicine, surgery, and midwifery, which means that he may, if he desires, open a medical hall. This, however, applies only to those who are qualifying to become doctors, not to pharmaceutical chemists. The Hall is an examining body only.

POSTGRADUATE EDUCATION

The universities and medical schools are responsible for most of the arrangements for postgraduate courses and other instruction facilities. Such courses will be found normally advertised in the medical press by the various organizations and authorities that provide them. Courses are for general practitioners (ranking for Ministry grant) are arranged in London by the British Postgraduate Medical Federation (see below); in universities other than London by the deans of the faculties of medicine or directors of

postgraduate studies, to whom application for further information should be made.

BRITISH POSTGRADUATE MEDICAL FEDERATION

The British Postgraduate Medical Federation (University of London) provides postgraduate education in the medical and dental specialties, supplementing the opportunities available at the undergraduate schools and teaching hospitals, and those provided by the three Royal Colleges. All postgraduates, including those from the Commonwealth and Colonial territories, and from foreign countries, may obtain the advice of the staff of the central office of the Federation (18, Guilford Street, London, W.C.1) on programmes of study. In addition to the Postgraduate Medical School of London at Hammersmith Hospital, with its university departments of general medicine, general surgery, and pathology, there are fourteen postgraduate institutes comprising the Federation. The provisions for study made by these are detailed below.

The Federation and its Institutes

Each of the institutes of the Federation is associated with a special postgraduate teaching hospital or with one of the Royal Colleges. The number of students who can be admitted to the clinical practice of these hospitals is limited. Resident clinical appointments are available to suitable students of the institutes and provide the most suitable form of postgraduate education. Selected graduates have opportunity for research. At all the institutes instruction is given throughout the academic year; it is suitable for graduates in the early stages of their specialist education and also for those who have completed their practical training. Two or more years of hospital work in general medicine and general surgery after graduation are normally advisable before beginning work in the special branches. The work at the institutes is of an advanced type and is comprehensive enough to enable graduates with suitable practical experience to prepare for higher degrees and diplomas. Emphasis is placed on clinical and laboratory teaching, supplemented by lectures and demonstrations. Each institute has a reference library and takes the current journals of its specialty.

Most of the institutes run short courses for consultants, and many of them have one-day courses for registrars. Regular programmes of these courses are available for each academic year. Short courses and other forms of continuing education for general medical and dental practitioners and local authority medical officers are arranged at hospitals throughout the four metropolitan regions, with the assistance of the advisers in postgraduate medical and dental education.

Postgraduate students from abroad are advised to make their arrangements well in advance. Those who desire the assistance of the central office of the Federation should get in touch with the director, Professor Sir Francis Fraser, at the address given above, as far in advance of their arrival in this country as possible. Those sponsored by their universities, Governments, or other official bodies receive first consideration in the allotment of vacancies. Established specialists from overseas who are here for a short time, and who wish to see something of the practice of the country, are always welcome; they are regarded as visiting colleagues, and the experts in their specialties are always ready to receive them and let them see the work and teaching being carried on. An information bureau of postgraduate activities in London and other university centres is maintained at the central office.

The Federation awards annually to graduates working in medical and dental schools or teaching hospitals of the University of London a number of travelling fellowships for the purpose of travelling abroad.

Each year the Federation arranges a series of advanced lectures entitled "The Scientific Basis of Medicine." These are delivered at 5.30 p.m. on Tuesdays and Thursdays at

the London School of Hygiene and Tropical Medicine, during the autumn and winter terms.

Postgraduate Medical School of London

The Postgraduate Medical School (Ducane Road, London, W.12) is associated with Hammersmith Hospital. The school is restricted to the medically qualified. It aims at the academic ideal of education rather than teaching, and is directed primarily to the training of teachers and specialists in general medicine, surgery, anaesthetics, pathology, and radiology. The work of the department of medicine is based on advanced clinical studies, supplemented by conferences, lectures, and discussions, with an emphasis on the scientific aspect of investigation and treatment. In the department of surgery the work is similarly arranged for the intimate clinical education of small groups in all aspects of surgery. The organized work of the clinical departments is concentrated into three university ten-week terms, starting in January, April, and October, leaving the vacations for more intensive research work. Research students are accepted for training and practice in methods of clinical investigation. The ordinary practice of the hospital is continuous throughout the year, but those not familiar with the school are advised not to start work in vacation-time. The clinical departments do not attempt to restrict the teaching to the needs of any particular examination curriculum, though it is of the proper standard for those working for higher degrees and diplomas. A year's comprehensive training in anaesthetics is provided. The work of the department of pathology includes a year's course for the university diploma in clinical pathology for which 16 students with pathology experience are selected. The hospital departments of radiology train doctors for the radiological diplomas. All these activities start in October. Many house officer and registrar posts are available in the appropriate departments.

The Specialist Institutes

The Institute of Basic Medical Sciences (Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2) comprises departments of anatomy, physiology, and pathology of the Royal College. It co-operates with other specialist institutes of the Federation in providing facilities for practical work and instruction in basic medical sciences, and provides opportunities for research for selected graduates. Full-time or part-time courses of fourteen weeks' duration, suitable for candidates for higher degrees and diplomas, begin in January and September.

The *Institute of Cancer Research* (Royal Marsden Hospital, Fulham Road, London, S.W.3) comprises the Chester Beatty Research Institute and parts of the departments of physics and radiotherapy at the Royal Marsden Hospital. The institute is concerned with all aspects of research into the causation and treatment of cancer, with the training of research workers in this field, and with advanced teaching in biophysics, radiotherapy, and problems of atomic energy. There are laboratories for chemical, biochemical, and histological investigations into cancer and allied diseases. Facilities are afforded to those wishing to pursue research into the clinical and pathological aspects of cancer or the physical and biological foundations of medical radiology, and who may be working for higher degrees such as the Ph.D. The department of radiotherapy gives a lecture and demonstration course of one week's duration in May and November annually, primarily for doctors from overseas, and accepts candidates to train for the diploma in medical radiotherapy. A course of lectures for students studying for the M.Sc. degree in biophysics commences in October.

The Institute of Cardiology (35, Wimpole Street, London, W.1) is associated with the National Heart Hospital. Six appointments in senior registrar and registrar grades are available in the hospital and the institute to provide specialized training for postgraduates who have already a sound grounding in general medicine. Full-time and part-time courses of instruction of about eleven weeks' duration are held twice annually, starting in April and October, and

two or three short intensive courses of lectures and demonstrations are held each year in February, June, and November; one of these is reserved for general practitioners.

The *Institute of Child Health* (The Hospital for Sick Children, Great Ormond Street, London, W.C.1) is associated with that hospital and with the Postgraduate Medical School at Hammersmith; the Queen Elizabeth Hospital for Children, Hackney, also participates in the clinical teaching. The Province of Natal Model Welfare Centre offers facilities for the study and care of the healthy child. The institute provides tuition throughout the year in three terms of **three** months each; in addition a series of lectures by specialists is given each term. Clinical clerkships are available for selected students.

The *Institute of Dental Surgery* (Eastman Dental Hospital, Gray's Inn Road, London, W.C.1) trains dental practitioners in the special branches of preventive and therapeutic dentistry. For candidates preparing for the F.D.S. of the Royal College of Surgeons, courses lasting eight months are held twice yearly, beginning in October and April.

The *Institute of Dermatology* (St. John's Hospital for Diseases of the Skin, 5, Lisle Street, London, W.C.2) gives clinical teaching daily throughout the year in the out-patient department, and instruction is given twice weekly at the in-patient department at Homerton. Tutorials in clinical dermatology and histopathology of the skin are given twice weekly during term time. There are also facilities for study and tuition in pathology, including mycology, and in radiotherapy and physiotherapy. Advanced students can apply for clinical and research assistantships, the former of which are competitive. In each of the university terms there is a series of lectures and a weekly clinical demonstration. Special short courses in histopathology and in medical mycology are also held. A discussion on cases of special interest, to which students attending the courses are invited, takes place once a week.

The *Institute of Diseases of the Chest* (Brompton Hospital, London, S.W.3) is associated with the Brompton and London Chest Hospitals. A comprehensive full-time course is conducted for a limited number of graduates who are specializing in chest disease, during the two terms beginning in October and January and a more selective one during the summer term. A larger number can be accepted for a part-time study, which is suitable for those reading for higher medical diplomas. Clinical instruction in thoracic surgery, including cardiac surgery, is given throughout the year, and there are courses in the October and January terms. Part-time instruction in radiology of the chest is given, and lectures and demonstrations open to the medical profession are held each week.

The *Institute of Laryngology and Otology* (330-332, Gray's Inn Road, London, W.C.1) is associated with the Royal National Throat, Nose and Ear Hospital. There is daily clinical teaching throughout the year. Whole-time courses held twice yearly include: basic sciences (three months), intensive lecture course (six weeks), practical revision course (two weeks), and advanced revision course (two weeks). Short courses on endoscopy, audiology, pathology, aural surgery, and malignant conditions are held occasionally.

The *Institute of Neurology* (National Hospital for Nervous Diseases, Queen Square, London, W.C.1) is associated with the National Hospital and the Maida Vale Hospital for Nervous Diseases. Teaching is mainly by attendance on hospital practice, supplemented by lectures and demonstrations. Two courses in clinical neurology are held annually, beginning in January and October. Clinical instruction in neurosurgery is given throughout the year. A course in the techniques of clinical neurophysiology is held annually in the summer months.

A course in the technique and clinical application of electroencephalography is held jointly with the Institute of Psychiatry twice a year. Courses of clinical demonstrations (two-weekly) are held several times a year. **Advanced** students are appointed as clinical clerks in the wards or attached to the special departments and research laboratories.

The *Institute of Obstetrics and Gynaecology* (Chelsea Hospital for Women, Dovehouse Street, London, S.W.3) is associated with Queen Charlotte's, the Chelsea Hospital.

and the department of obstetrics and gynaecology at Hammersmith Hospital. Teaching is based on ward work, supplemented by lectures and demonstrations during two terms of **thirteen weeks' duration** which begin in March and September. For students preparing for higher qualifications, two intensive courses of **a fortnight's duration** are held in June and December. A week's course for general practitioners is held twice a year.

The *Institute of Ophthalmology* (Judd Street, London, W.C.1) is associated with the Moorfields Eye Hospital. In addition to teaching by means of attendance on the hospital practice, a routine lecture and tutorial course, normally covering two terms of approximately sixteen weeks each, is held twice a year, commencing in March and October; the first part of the course is devoted to anatomy, embryology, histology, physiology, optics, and elementary clinical instruction; the second part comprises bacteriology, pathology, operative surgery, medical ophthalmology, and all aspects of ophthalmic disease. Introductory courses, lasting one week, in orthoptics and contact-lens practice are held during each term. Clinical teaching and lectures are given for advanced students, and there are facilities for research for suitably qualified candidates.

The *Institute of Orthopaedics* is associated with the Royal National Orthopaedic Hospital (234, Great Portland Street, London, W.1). Training in orthopaedics to selected graduates who have already been trained in general surgery and the basic sciences is afforded by means of clinical appointments, with opportunities for research. Short advanced courses for graduates with practical experience are held at various times during the year. Twice a year, in the spring and the autumn, a short revision course of a week's duration in advanced clinical orthopaedics is held. Both the central hospital in Great Portland Street and the country hospital are attended by postgraduate students.

The *Institute of Psychiatry* (Maudsley Hospital, Denmark Hill, London, S.E.5) is associated with the Bethlem Royal and Maudsley Hospitals. Training normally covers three years, after experience elsewhere in general medicine, and is based on responsible hospital duties under supervision. Regular series of lectures and demonstrations are given throughout each of the university terms. Clinical training continues throughout the year and includes seminars and case discussions. Students who, because of previous experience, do not wish to take the comprehensive course are able to attend a limited series of lectures and clinical instruction. For those who wish to specialize in child psychiatry a six-months course is held twice a year. A year's course in abnormal psychology for the university post-graduate diploma in psychology is available to holders of an honours degree in psychology. There are facilities for original investigation under supervision in the clinical and other departments.

The *Institute of Urology* (10, Henrietta Street, London, W.C.2) is associated with St. Peter's, St. Paul's, and St. Philip's Hospitals. Comprehensive instruction is given in the wards, out-patient departments, operating theatres, and laboratories throughout the year. Week-end courses of demonstrations and lectures are arranged for higher examination candidates. Occasional lectures on venereology are arranged with the Medical Society for the Study for Venereal Diseases, and arrangements can be made for graduates to attend venereal diseases clinics. In the winter months lecture-discussions on urological subjects of interest to the whole profession are held on Wednesday evenings at 5 o'clock. Limited numbers of clinical assistants are appointed to individual surgeons for personal tuition, and there are also research assistantships.

Fellowship of Postgraduate Medicine

The Fellowship of Postgraduate Medicine (60, Portland Place, London, W.1) provides general information on post-graduate work available both in London and in provincial centres, and itself arranges a certain number of courses of instruction at hospitals in or near London. These courses

are specially designed to be helpful to candidates for higher degrees and diplomas, though attendance at them is not restricted to such candidates. The courses include general medicine, general surgery, obstetrics and gynaecology, and children's diseases. Some are full-time, lasting for one or two weeks, but the majority are part-time and are intended particularly for postgraduates not free for full-time study.

The Fellowship also arranges week-end courses, occupying the whole of a Saturday and Sunday, in such subjects as general medicine, general surgery, orthopaedics, plastic surgery, rheumatic diseases, and infectious diseases. Although these are primarily intended for candidates for higher degrees, many of them are also suitable for, and attended by, general practitioners. The Fellowship is an independent body, and is not connected in any way with official arrangements for postgraduate instruction under the National Health Service.

COLLEGES IN LONDON

Royal College of Physicians

The Royal College of Physicians of London was founded in 1518 so that "none should be allowed to practise physic but those deeply studied therein," and the chief interest of the College is still the maintenance of a high standard of medical practice. The licence (L.R.C.P.) is granted after examination in association with the membership of the Royal College of Surgeons of England. Members (M.R.C.P.) are elected after passing a postgraduate examination. Fellows (F.R.C.P.) are elected annually from among the members, no examination being required. The College jointly with the Royal College of Surgeons conducts examinations for postgraduate diplomas in anaesthetics, child health, industrial health, laryngology and otology, medical radiodiagnosis, medical radiotherapy, ophthalmology, pathology, physical medicine, psychological medicine, public health, and tropical medicine and hygiene.

Each year about twenty lectures are held which are open to all members of the profession. This year, it has been decided to arrange conferences which, it is hoped, will be held from time to time on topics of scientific interest to consultant physicians. These conferences are designed especially for physicians in peripheral hospitals who wish to keep in touch with the latest developments. The first of these conferences on "Anaemia and the Alimentary Tract" was held in July (see *Journal*, August 2, p. 301); the second, on a subject to be announced, is to be held early next year.

The College has sponsored the foundation of the Association for the Study of Medical Education. The first conference of this body will be held at the College on September 25 and 26, when the subject for discussion will be "Experiment in Medical Education." The College also administers scholarships and grants for medical research. These are usually worth at least £1,000 per annum and are awarded for three years, and, although some of the scholarships are restricted, in all they cover a wide field of medical subjects. From time to time the College publishes reports on subjects of topical interest. This year a report has been published on electroencephalography.

Royal College of Surgeons

The origin of the Royal College of Surgeons of England is to be found in the history of two corporations which flourished in the City of London six hundred years ago and more, the Barbers' Guild and Fellowship or Guild of Surgeons. After a long period of rivalry the two corporations composed their differences and were granted an Act of Union by King Henry VIII in 1540. Disharmony between the Barbers and Surgeons recurred and increased until in 1745 an Act of Parliament established two separate companies. In 1880 the Company of Surgeons was reconstituted by Royal Charter into the Royal College of Surgeons of London (the name was changed into its present form in 1843) and left the City to take up its present position in

course in general surgery, 19 in orthopaedic surgery, 15 in public health, 11 in anaesthesia, 12 in psychological medicine, 25 in radiodiagnosis, 7 in radiotherapy, 4 in venereology, 67 in tropical medicine and hygiene, and 22 in the part-time M.R.C.P. course recently established. The course in general surgery is suitable for candidates who have already passed the primary examination for the F.R.C.S., but candidates for the course in orthopaedic surgery must already hold the F.R.C.S., to become eligible to take the examination for the M.Ch.Orth. degree. The courses leading to the D.M.R.D. and D.M.R.T. extend over two years; candidates are usually found registrar appointments during their second year. During the course in anaesthesia students are found appointments in recognized general hospitals for the purpose of gaining practical experience. Further information regarding university postgraduate courses may be obtained from the dean of the faculty of medicine.

At *Manchester University* courses for the diplomas in psychological medicine, public health, radiodiagnosis and radiotherapy have been held. The course for the diploma in bacteriology, however, will not be held in the coming session. A one-year course in medical statistics is also available. Refresher courses in industrial health have been held, and a series of lecture-demonstrations for general practitioners, which were held on alternate Sunday mornings, were very successful. These were given in conjunction with the College of General Practitioners, and a similar series will be given this autumn. The dean of postgraduate medical studies is Mr. R. L. Newell, who is available for consultation by appointment.

At the *University of Bristol* the degrees of M.D., Ch.M., and Ph.D. are open to graduates of other universities, but only to those graduates who have pursued original research in the university for not less than two years, and in effect this regulation means that these higher degrees are open only to those graduates of other universities who hold appointments on the staff of Bristol University or one of the local hospitals. The university diploma in psychological medicine is in abeyance. The university offers a diploma in public health, and a course for it will be held this session. A few postgraduate students are accepted for training for the D.M.R.D. and D.M.R.T. (Conjoint), and arrangements can sometimes be made for suitable candidates to hold a part-time post in the Bristol hospitals while doing the course. A course in child health lasting three months usually begins in October of each year, but this year is not being held. Refresher courses for general practitioners consist of Sunday morning lecture-demonstrations in Bristol and occasional intensive week-end courses at hospitals in various parts of the South-Western region. A postgraduate course in medical physics for science students has been instituted. A review of pre-registration appointments has been undertaken to ensure that only house officer posts which have the facilities necessary for sound postgraduate training are recognized for the purpose. A medical postgraduate dean has been appointed.

At the *University of Leeds* extended refresher courses for general practitioners, comprising one half-day session a week for six weeks and week-end refresher courses on special topics, are arranged from time to time, both in the teaching hospitals and in regional hospitals. The university grants a diploma in public health, also a diploma in psychological medicine, the part-time course for which covers eight academic terms. The secretary of the Postgraduate Committee is Dr. T. A. Divine, School of Medicine, Thoresby Place, Leeds, 2.

At *Sheffield University* the recently resuscitated D.P.H. course was successfully concluded last session, but for various reasons it is not proposed immediately to commence another. The development of the department of psychiatry, to which reference has already been made, has enabled the department to become increasingly a focus for regional postgraduate education in this specialty. Other postgraduate activities continue along the lines previously described, though the experiment is being tried, at the time of writing, of holding the usual intensive refresher course for general

practitioners in the hospitals of the Nottingham area instead of in Sheffield as in past years.

At the *Welsh National School of Medicine* one of the postgraduate diplomas which attracts many students from overseas—namely, the tuberculous diseases diploma—will in future include chest diseases generally, its title being changed to the diploma in tuberculosis and chest diseases (D.T.C.D.). This is the first step in developments which are contemplated in the department of tuberculosis.

SCOTTISH UNIVERSITIES

Postgraduate Facilities at Edinburgh

Edinburgh University holds postgraduate courses leading to the diplomas in medical radiodiagnosis (2 years), medical radiotherapy (2 years), psychiatry (6 months, full-time), public health (9 months), and tropical medicine and hygiene (6 months, see below). Graduate scholarships and fellowships are also offered, being open to graduates in the faculty of medicine of any university, to graduates in the faculties of arts or science of any university who hold an honours degree, and to licentiates in medicine. The holders of such awards are required to undertake research work in a department within the faculty of medicine. In addition, the Edinburgh Postgraduate Board for Medicine, which is an advisory council to the university, provides courses of instruction leading to the higher qualifications granted by the Royal Colleges of Edinburgh. These are advertised at intervals in the medical press, and full particulars can be obtained from the director of postgraduate studies, Surgeons Hall, Edinburgh, 8. In addition the board arranges library facilities and clinical work and helps the postgraduate students in a variety of ways. The courses of instruction are considered to be of value to those requiring a period of revision or those preparing for higher diplomas.

In the medical sciences a 12-weeks course begins at the end of June. This includes lectures and practical instruction in anatomy, physiology, pathology, biochemistry, and bacteriology. The instruction is of an advanced standard and students should already be well grounded in these subjects. In addition two 10-weeks courses are arranged to start in October and February. In surgery there are two 12-weeks courses each year, beginning in March and September. The numbers are limited and the instruction is primarily clinical in nature. In medicine there are two similar 12-weeks courses. The instruction is systematic, clinical, and by demonstrations. From July to September a course in clinical medicine is arranged in which clinical instruction in small groups is given in the teaching medical units in Edinburgh. For those already holding higher qualifications short intensive courses in special subjects are held from time to time. Advanced courses in endocrinology and gastro-enterology are being arranged to take place in March, 1959. The numbers on these courses are limited so that discussion can be free. Through the director of postgraduate studies, postgraduate students may be attached for clinical duties to the medical and surgical units in Edinburgh, preference being given to those who have attended the courses.

A two-weeks refresher course for general practitioners is held at Edinburgh in May, giving a wide variety of instruction in medicine, surgery, and obstetrics. There are also occasional one-day courses in selected subjects, and a series of clinical meetings arranged for the general practitioners of the South-East Region of Scotland. In addition, there are occasional courses specially arranged for anaesthetists.

The Royal College of Surgeons of Edinburgh (18, Nicolson Street) has a two-part examination for its fellowship.

Postgraduate Facilities at Glasgow

Glasgow University Postgraduate Medical Education Committee, representing the University and the Royal Faculty of Physicians and Surgeons of Glasgow, is offering

the following courses during the coming session. A nine-weeks' part-time course of instruction in anatomy, physiology, biochemistry, pathology, and bacteriology will be held, as in previous years, from October to December. The course is suitable for candidates preparing for the primary examinations for the surgical fellowships, and will provide a total of approximately 180 hours of instruction. The course is organized primarily for the junior staff of hospitals in the Western Region of Scotland, but it is also open to other applicants. A modified form of the course is available for trainees in anaesthetics reading for the primary examination of the F.F.A. Clinical attachments to teaching units of one to three months' duration can be arranged in general medicine, general surgery, and various specialties for those proceeding to higher qualifications.

An annual course for the diploma in public health is available, and a course for the diploma in industrial health will be arranged in any year in which there are sufficient applicants. Short courses in other specialties are arranged when the demand arises and are advertised in the medical journals. For the ensuing session a three-weeks course in mental deficiency and two week-end courses in chemotherapy have already been arranged. The department of psychological medicine will hold a part-time course, extending from January to June, 1959, for candidates reading for the D.P.M. Training in radiodiagnosis and radiotherapy, recognized for the D.M.R.(D.) and D.M.R.(T.) is available. At least two refresher courses for general practitioners are held each year. A very successful addition to the range of postgraduate courses has been the institution of short intensive courses on the use of radioactive isotopes. These courses are organized by the staff of the Regional Physics Department, which advises and assists hospitals on matters concerned with isotopes and electronic apparatus.

The Royal Faculty of Physicians and Surgeons of Glasgow grants, after examination, a fellowship *qua* physician and a fellowship *qua* surgeon. The examinations are clinical, written, and oral.

Universities of St. Andrews and Aberdeen

At *St. Andrews University* a combined clinical and medical sciences course will be held from October to March at Queen's College, Dundee. All who take this course will have a clinical attachment in one of the 16 specialist subjects of their choice and a supervisor. The object of the course is to bring postgraduate students up to date with the current trends in the medical sciences which are of importance to future medical developments. In addition there are weekly open postgraduate lectures by distinguished visitors and a course of lectures on scientific methods. There is also a postgraduate course in anatomy and physiology (including biochemistry) at St. Salvator's College, also lasting from October to March. Details of these courses may be obtained from the dean of the medical faculty.

At *Aberdeen University* there are courses for general practitioners. Once a year there is a full-time course of a fortnight's instruction, and part-time courses in the various specialties are held once a week during each term. Apart from the instruction given to registrars in preparing them for examinations for higher qualifications, there are no organized courses for such people, but anyone who is interested may be taken on to do postgraduate study in the various departments.

HYGIENE AND TROPICAL MEDICINE

The London School

The London School of Hygiene and Tropical Medicine (Keppel Street, Gower Street, W.C.1) is a postgraduate school of the University of London, devoting its attention to teaching and research in preventive medicine and occupational health, bacteriology, and the whole range of subjects concerned with tropical medicine and hygiene. The work of the school is organized in ten main departments: applied physiology, bacteriology and immunology, bio-

chemistry, clinical tropical medicine, entomology, human nutrition, medical statistics and epidemiology, parasitology, public health, and the Ross Institute of Tropical Hygiene.

The research work has many links with other institutions at home and abroad. On the teaching side the school prepares students for four academic postgraduate diplomas of London University: applied parasitology and entomology, bacteriology, public health, and tropical medicine and hygiene. These courses occupy a whole academic year. The school also provides a five-months course for the Conjoint Board's D.T.M.&H. Teaching for the University of London postgraduate D.P.H. is designed to develop the student's knowledge of principles of preventive medicine and to bring him in touch with practical issues of public health administration. Much of the work is in the form of practical instruction against the background of the British health services, and arrangements are made for the students to visit health areas in both urban and rural districts and to study central administration. The study of British health services is intended to illustrate the broad principles of public health in such a way as to render the course appropriate to students from both home and overseas. In addition to the subjects covered by the D.P.H. syllabus the students may take one of the following special subjects: child health, medical statistics and epidemiology, mental health, occupational health, tropical hygiene, and nutrition. The special subject of occupational health, together with the general teaching for the D.P.H., fulfil in part the requirements for entry to the examination for the D.I.H.

The course for the University of London postgraduate diploma in bacteriology provides advanced instruction for graduates in medicine, science, and pharmacy, and for others with suitable qualifications, who intend to follow a career in bacteriology. The course begins in October and lasts for nine months. The course for the Conjoint Board's D.T.M.&H. is of five months' duration and is held twice a year. The course for the University of London academic postgraduate D.T.M.&H. occupies an academic year. There is a preliminary course of approximately four and a half months for the Certificate in Tropical Medicine and Hygiene commencing at about the beginning of October each year. The final part of not less than four months consists of advanced study in one of the following two fields—clinical tropical medicine and tropical hygiene.

The course for the University of London postgraduate certificate and diploma in applied parasitology and entomology, planned mainly for those wishing to take up research or laboratory appointments abroad, is held annually commencing in October. Graduates in medicine, veterinary medicine, veterinary science, and science, and those with approved non-graduate qualifications in medicine and veterinary medicine, are eligible. The full course lasts for nine months.

A course in statistical methods applied to medicine and epidemiology is held annually on two days a week from approximately the beginning of March to the end of June. Students without a medical qualification can be accepted. A ten-weeks course in environmental control is held twice a year, commencing at approximately the beginning of March and October. Although intended primarily for health inspectors from abroad, the course is so planned as to be of value to medical officers and others interested in the health aspects of environmental control both at home and abroad.

Royal Institute of Public Health and Hygiene

The Royal Institute of Public Health and Hygiene (28, Portland Place, London, W.1) conducts recognized courses of instruction for the diploma in public health and for the diploma in industrial health. The next courses will start on September 12. All tuition may be taken as whole time or part-time study. Part-time study may be commenced at any time. Clinical tuition in general medicine at a postgraduate medical teaching hospital is available and may be undertaken optionally. The examinations are those of the Conjoint Board of the Royal College of Physicians of

London and the Royal College of Surgeons of England for both diplomas, and, in addition, of the Society of Apothecaries of London for the D.I.H.

Liverpool School of Tropical Medicine

Men and women students of any nationality who hold a medical qualification approved by the university are admitted at the Liverpool School of Tropical Medicine (Pembroke Place, Liverpool) to examination for the D.T.M.&H. (Liverpool). A complete course of instruction lasting about three months is given twice yearly. The examination is held in December and April, and consists of two papers on tropical medicine (including pathology and bacteriology), one on parasitology, one on entomology, two on tropical hygiene and related subjects; and practical and oral examinations in tropical medicine, parasitology and entomology, and tropical hygiene. The dates of the courses are September to December and January to April. The school also gives courses in parasitology and entomology for students taking the D.P.H.

Tropical Medicine at Edinburgh

There is no separate school of tropical medicine at Edinburgh University, although there is a department in that subject. Other departments also contribute to the courses of instruction leading to the diploma in tropical medicine and hygiene. The primary course is held in the autumn and the secondary course in the spring. The former comprises systematic instruction and practical work in the diseases of tropical climates, entomology, parasitology, bacteriology, and vector control. The secondary course provides further instruction in diseases of tropical climates and also in tropical hygiene, virology, applied physiology, venereal diseases, tuberculosis, and elementary statistics. Clinical instruction is given in the wards of the Eastern General Hospital and the other classes are held in the appropriate university departments. Examinations are held at the end of the primary and secondary courses. Candidates who have passed the examination at the end of the first term may interrupt their course and take the secondary course at a later date.

OTHER COURSES AND EXAMINATIONS

The *Tavistock Clinic* (2-4, Beaumont Street, London, W.1) is an out-patient clinic for psychotherapy of neurotic and personality disorders, both of adults and of children. Registrar and senior registrar appointments, in both the adult department and the department for children and parents, provide systematic training in these fields. Personal analysis is available to such trainees in the adult department. There are also the following extramural courses: (1) a two-year part-time introductory course in psychotherapy, including psychopathology and group experience, open to selected trainees from other National Health Service institutions; (2) seminars at introductory and more advanced levels for general practitioners and consultants in principles of psychological medicine and the doctor-patient relationship, including case supervision for those who want experience in treating neurotic and psychosomatic disorders in their own practices. There are also courses in Rorschach testing (open to psychiatrists), and for clinical psychologists, social workers, and child psychotherapists (non-medical). The clinic welcomes visitors, and has some facilities for offering associate status to interested overseas psychiatrists, psychologists, and social workers who are in Great Britain for further training. Full particulars may be obtained from the training secretary at the above address.

The *National Association for Mental Health* (39, Queen Anne Street, London, W.1) organizes, with the extramural department of the University of London, courses on educationally subnormal children and mental defectives for school medical officers. The course includes lectures on normal child development, the pathology and causation of intellectual retardation and maladjustment, the psychology of

educationally subnormal children, and educational and social implications of backwardness. A year's course is organized for men and women wishing to train for work in occupation centres and "school departments" of mental deficiency hospitals. Lectures and courses for social workers, health visitors, and teachers are also held.

The *Institute of Psycho-Analysis* (63, New Cavendish Street, London, W.1) furnishes a part-time course lasting about four years in psycho-analytic theory and technique. It includes personal analysis, attendance at lectures and seminars, and clinical work under supervision. General psychiatric experience must be obtained at other clinics or hospitals, since the teaching at the institute is confined to psycho-analysis.

The *Society of Analytical Psychology* (25, Park Crescent, London, W.1), founded in 1945, is the professional body representing Jungian psychology in this country, and is a training centre for analytical psychology with C. G. Jung as its President. For some years the society has operated a part-time course of training in analysis. This consists of two parts. Candidates accepted for Part I undergo a personal training analysis for at least two years. Later, if accepted for Part II, candidates attend a two-year course of seminars on clinical practice, the theoretical aspects of analysis, and an introduction to mythological material in relation to medical psychology. In addition each candidate begins to treat cases under the supervision of a training analyst. Election to associated professional membership takes place when the candidates have fulfilled certain minimum requirements with regard to the length of their personal analysis and supervision period, and when they are considered competent to treat cases without supervision. For its own members the society gives the opportunity of participation in lectures, seminars, and research groups concerned with problems of adult and child analysis.

A course of instruction in homoeopathy for medical practitioners and senior students, arranged by the *Faculty of Homoeopathy*, begins at the Royal London Homoeopathic Hospital (Great Ormond Street, W.C.1) on October 9. It includes lectures on homoeopathic prescribing and on homoeopathy in theory and practice, also clinical tutorials for practical instruction in homoeopathic practice. The lectures deal with subjects required for examination for the Diploma of Membership of the Faculty.

CAREERS IN RESEARCH AND THE SERVICES

Medical Research Council

The Medical Research Council (38, Old Queen Street, London, S.W.1), originally established in 1913 as the Medical Research Committee, is appointed to administer the funds provided annually by Parliament for the promotion of research in medical science. The Council is under the general direction of the Committee of Privy Council for Medical Research, of which the Lord President is the chairman and the Minister responsible to Parliament. The Council is not constitutionally a Government department; it selects and appoints its own staff, who are not civil servants. The scientific staff of the Council work in some 70 establishments located mainly in hospitals and universities in Great Britain, and Uganda. The total scientific staff of the Council numbers nearly 700, of whom about one-half are medically qualified. Its research establishments vary widely in size; the largest is the National Institute at Mill Hill, but the average research unit consists of from five to ten scientific workers with a number of technical and clerical assistants. Arrangements have been made by the Council, in consultation with the Health Departments and with the advice of the Clinical Research Board, for the development of research in the

The aim of the Council is to provide the opportunity for careers which are equivalent to those offered in the universities to men and women of equal ability and experience; the Council's salary scales for scientific appointments are based on this principle. New appointments to the scientific staff, except in the case of senior posts, are normally made for definite periods, usually of three or five years at a time. In addition to maintaining its own staff, the Council makes available short-term grants in support of specific research projects carried out by independent workers in universities, hospitals, and elsewhere. The Council also awards clinical research fellowships, scholarships for training in research methods, and certain travelling fellowships; these last are awarded either on an agency basis for other bodies or from private benefactions entrusted to the Council.

Pamphlets dealing with the constitution and functions of the Council, and describing opportunities for service on its staff, are obtainable from the Council's headquarters office.

Public Health Laboratory Service

On behalf of the Ministry of Health the Medical Research Council administers the Public Health Laboratory Service, which was originally set up as an emergency service in 1939 and has since become permanent; there are about 60 separate laboratories in England and Wales.

In addition to their more routine duties, members of the staff of the service, whose salary scales are normally equated with those of the National Health Service, undertake research problems in bacteriology and epidemiology. Furthermore, the service maintains a number of special laboratories which act as reference centres for particular infections, and these engage largely in research.

Naval Medical Service

"Naval medicine" comprises a variety of subjects including the physiology of diving, the physical aspects of service afloat and ashore, commando service, tropical diseases, and industrial hygiene; an important further specialty is that of aviation medicine, and a small number of naval medical officers undergo full pilot training before undertaking duties with the Fleet Air Arm or in research establishments. The naval medical officer is not concerned solely with the welfare of the sailor, but also with the families of Service men and of Admiralty personnel serving abroad. Officers on the permanent list are encouraged to specialize in all branches of medicine and are given full facilities to obtain higher qualifications. Courses of postgraduate study are carried out both in naval hospitals and at civilian teaching centres.

Service on the active list is up to the age of 55 for all officers, 57 for surgeon captains, and 60 for surgeon rear-admirals. Previous experience, both Service and professional, is counted in assessing seniority—previous commissioned service as a medical officer in one of the armed Forces counts in full, and non-medical commissioned service counts as to half. Civilian hospital experience and also some medical experience in private practice may be allowed to count up to a limit of seven years in all. Officers serving in the United Kingdom are granted 42 days' leave per annum on full pay and allowances, with three free travel warrants. If serving overseas local leave is given at the rate of 14 days a year, and foreign service leave at the rate of two days for each month is allowed on returning to the United Kingdom. Leave for officers serving in H.M. ships on general service is at the rate of three days for each month.

All entries at present are being made as short commissions in the first instance. Short service consists of either three or four years, during which period a medical officer becomes eligible to apply for a surgeon lieutenant R.N., and is eligible to apply for a transfer with full seniority to the permanent list. Officers who transfer to the permanent list after a minimum of one year's service will be paid a grant of £1,500 (taxable). The normal career of a medical officer enables him to be promoted to the full rank of surgeon lieutenant after one

year's service and to surgeon lieutenant-commander after a further seven years' service. In the normal course surgeon lieutenant-commanders are promoted to surgeon commanders by selection at about their fifteenth year of total service, and surgeon commanders to surgeon captains at about their twenty-third year of total service.

Further information may be obtained from the Medical Department, Admiralty, Queen Anne's Mansions, St. James's Park, London, S.W.1.

A Career in the R.A.M.C.

Two-thirds of medical officers in the Royal Army Medical Corps are employed on general-practitioner duties. After attending the junior officers' course at the Royal Army Medical College, Millbank, they start their career as regimental medical officers and they become conversant with the soldier and his environment, the objects of the Army, and the requirements from its medical service in peace and war. They will later serve overseas, where, as regimental medical officers or in charge of a medical reception station or small hospital, they will be able to study the causation, prevention, and treatment of tropical diseases, the effects of climate, and the like. On return to the United Kingdom they attend the senior officers' course, the first two and a half months being spent in study at Royal Army Medical College, Millbank, and the next three months undergoing a special postgraduate course at selected teaching hospitals. At this stage officers may opt to remain at general medical duties or take up field training or junior staff appointments. For the more senior appointments the requirements are a sound background of clinical and preventive medicine to meet their advanced responsibilities in the administration of the Army Medical Service in peace and war.

Specialists are, subject to professional proficiency, employed on specialist duties up to the rank of colonel. Thereafter they may serve in this rank up to the retiring age of 57 or may be selected for promotion to brigadier in either a specialist or non-specialist capacity. The process of selection for specialist training is carried out after the junior officers' course, those applicants who are most successful in the course examination being accepted. Those accepted are provided with excellent opportunities to obtain higher qualifications and specialist experience. At present ophthalmologists, otolaryngologists, and radiologists are especially required. There are liberal arrangements for specialists and non-specialists to undergo postgraduate training throughout their career.

All suitable medical officers, specialist or non-specialist, may be employed up to the age of 65 in appointments specially set aside for retired officers. Non-specialists are employed on general-practitioner or medical administrative duties and specialists on specialist duties.

Further information may be obtained from the Assistant Director General, War Office, A.M.D.2, London, S.W.1.

Medical Branch of the R.A.F.

The Royal Air Force offers an attractive career to both men and women medical practitioners who are British subjects or citizens of the Irish Republic. The normal upper age limit for applicants is 33, but older applicants may be considered. Appointment in the first instance is normally to short-service commissions for three, four, five, or six years, each of which may be extended to complete a maximum period of eight years. Exceptionally, suitable candidates may be appointed to permanent commissions direct from civil life. Short-service officers may apply for permanent commissions at any time during their service. Medical practice in the R.A.F. brings officers into contact with flying, and air evacuation of the sick and wounded as well as with the clinical specialties and the treatment of Service families. In addition, there are opportunities in aviation medicine, physiology, hygiene, and industrial health.

Officers serving on permanent commissions may be allowed study leave to take approved postgraduate courses, for which tuition fees on an approved scale may be granted. Officers having experience or aptitude in a specialty may be employed on specialist duties, if Service conditions permit, with the object of qualifying as junior specialists and subsequently earning recognition as R.A.F. specialists. A full career is possible in the clinical specialties with time promotion to group captain and additional specialist pay. Non-specialist medical officers below the rank of group captain may be awarded additional pay on gaining a registrable D.P.H., D.I.H., or D.T.M.&H., provided the prescribed period of study occupied an academic year. Non-specialist medical officers can expect time promotion to wing commander, with promotion to higher ranks by selection. Antedate of seniority up to a maximum of seven years may be admissible for civil experience and will count towards pay, seniority, and promotion.

Further information can be obtained from the Under Secretary of State for Air, Air Ministry, M.A.1, 1-6, Tavistock Square, London, W.C.1.

Prison Medical Service

The Prison Medical Service is a part of the general service class of the medical civil service, and is under the immediate control of the director of medical services at the Prison Commission. The work is mainly clinical and the medical officer is responsible for the physical and mental welfare of the inmates, a responsibility which extends to a general oversight of the hygiene of the establishment in which he is working. The service is expanding to meet the needs of a rising inmate population and the increased demands of present-day methods. It offers an attractive career to medical practitioners who are interested in the various problems connected with crime and the understanding and treatment of criminals. The medical and surgical cases seen are comparable with those met with in outside practice. The various establishments have their own hospital accommodation; a large prison, for example, may well have a hospital with up to 100 beds.

The doctor in a prison or borstal is a member of a team whose efforts are directed towards the rehabilitation of those committed to its charge. On the medical side the aim is not only to attend to ordinary day-to-day medical care but to discover, and if possible to remedy, disabilities and maladjustments which hinder the training of the offender and make it more difficult for him to regain a place among law-abiding citizens. Although not himself in the National Health Service the prison medical officer maintains a close liaison with the hospital and specialist facilities of that Service.

There are now over 70 establishments under the control of the Prison Commissioners and they vary very much in their size and purpose, depending on the class of inmate, and their medical requirements differ accordingly. At the larger establishments the medical work is in the hands of whole-time medical officers, whereas the small institutions are served by part-time doctors who are usually local general practitioners. The more important prisons may have as many as four or five full-time medical officers, together with psychologists and assistants for psychological testing. Principal and senior medical officers have advisory and other duties in connexion with small groups of establishments. At a few prisons there are also psychiatric social workers. The medical officer is called upon to make medical and psychiatric reports to the Commissioners from time to time. In remand prisons the preparation of reports to court and the giving of verbal evidence, particularly in regard to the mental condition of offenders, are important aspects of the work. Postgraduate experience in psychiatry is therefore an advantage. Surgical and psychotherapeutic units are established at selected centres, where the work is undertaken mainly by visiting specialists working on a sessional basis and in close association with the regular medical staff.

The national scales of remuneration are in accordance with the general civil service scales. The appointments are pensionable, without contributions being required, and on retirement normally a pension and lump sum gratuity are payable. There is also a contributory widows' and children's pension scheme. Pensionable service under the National Health Service and established civil service may be aggregated for pension. Unfurnished quarters, when available, are provided at a moderate rental. Permanent appointments are made by the Civil Service Commission, 6, Burlington Gardens, London, W.1, to whom inquiries for such appointments should be addressed. On occasion temporary full-time appointments are available, and for such appointments, as well as for part-time appointments, particulars can be obtained from the Prison Commission, Horseferry House, Dean Ryle Street, London, S.W.1.

Overseas Civil Service

In the medical departments of the Governments of the territories overseas for which the Secretary of State of the Colonies is responsible, openings occur in all parts of the world. Many future appointments are likely to be made on the bases of short-term contracts, usually renewable. Doctors in the N.H.S. may take temporary appointments overseas up to six years without loss of pension rights. In some territories permanent appointments are available; candidates selected for these appointments become members of the medical branch of Her Majesty's Overseas Civil Service. Candidates must normally be British subjects whose names appear on the Medical Register, and should not be over 45 years of age.

Full terms and conditions of service may be obtained from the Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Missionary Service

For doctors with a call to dedicated service, the mission field offers great opportunity for the exercise of medical knowledge and skill where the need is greatest. Though the financial rewards are small, a Christian doctor will find this work immensely satisfying. Any who have this service in view are advised to spend eighteen months or two years in resident appointments after qualification. Special missionary training is required by some of the societies. Although long service is preferred, short-term offers are considered by most societies. Application may be made to any of the missionary societies, or to the Secretary of the Medical Advisory Board, Edinburgh House, 2, Eaton Gate, London, S.W.1, or to the Secretary, Medical Missionary Association, 31, Bedford Place, London, W.C.1.

OPENINGS IN INDUSTRIAL MEDICINE

Industrial medicine can be especially attractive to a doctor who is interested in preventive medicine and who wishes to do clinical work. It offers opportunities for treating the injured and sick, for the surveillance of vulnerable groups of workers such as the young and old, and those employed in dangerous trades, and also for studying the effects of the working environment on health. The doctor may also help to identify occupational hazards and control them. He often has the advantages of constructive criticism from colleagues, a close contact with other professions, and assistance from nurses and secretaries in the routine work. He has the material assets of holidays with pay, pension schemes, and definite hours of work, but he has to deal with emergencies and is expected to keep abreast with new knowledge by reading and by contact with professional societies. Industrial medical services are extensive without being comprehensive and, although they are not linked with the

National Health Service, many of the doctors working part-time in industrial medicine are general practitioners. In the United Kingdom there are approximately 400 whole-time and 3,000 part-time doctors in industry. In addition some 1,700 or more general practitioners are Appointed Factory Doctors who examine young persons and others employed in dangerous trades as required by law. Most of the industrial medical officers are employed in factories, but recently services have been developed in mines, transport undertakings, shops, and offices; many universities also have medical services for their students and staff. Medical services in industry have grown largely as a result of the voluntary enterprise of employers; some provide for no more than the treatment of casualties, while others fulfil the modern conception of occupational health—namely, to promote and maintain the highest degree of physical, mental, and social well-being for all types of workers.

Appointments in industrial medicine are frequently advertised. Salaries vary according to age, experience, and qualifications. Medical officers are usually either on a definite salary scale or receive increments in accordance with the growing value of their work and length of service. A few doctors who have the interest and abilities to do research and to teach in this field are employed by the Medical Research Council units and university departments of social and industrial medicine. Occasionally there are vacancies for medical inspectors of factories in the Ministry of Labour and National Service and for medical officers in the Ministry of Pensions and National Insurance. Many of these appointments are not easy to obtain, but a doctor who has a good experience of clinical medicine and some post-graduate training in preventive medicine has a good chance of becoming a whole-time industrial medical officer and of doing work which can be both fascinating and challenging.

The Association of Industrial Medical Officers was formed in 1935 to bring together doctors employed full-time in industrial medicine in order to promote scientific study and to provide mutual help. In 1941 doctors working part-time in industrial medicine were admitted as associate members. The total membership is now nearly 1,000 and there are 12 local groups in the United Kingdom which hold frequent meetings. In addition three meetings of the whole association are held every year, two in London and one in the provinces. The association has adhered to its original aim to confine itself to scientific and social activities. It publishes its own *Transactions*.

PROFESSIONAL ORGANIZATIONS

British Medical Association

The British Medical Association, which was founded in 1832, now comprises a membership of over 70,000, of whom about 16,000 are overseas. Its main objects are to promote the medical and allied sciences and to maintain the honour and interests of the medical profession. Although membership is entirely voluntary, 80% of practising doctors in this country are members and the Association can therefore claim to speak for the whole of the profession in its dealings with Government and other authorities.

The Association is often described as a federation of local medical societies known as Divisions. These are grouped in Branches. Every member is automatically included in the membership of the local unit in whose area he resides or practises. The Divisions hold regular meetings for clinical, social, or business purposes, and every member is entitled to take part in their activities.

Other privileges of membership of the Association include the receipt each week of the *British Medical Journal* and its *Supplement*, the latter being the official means of communication between Headquarters and the individual member. In addition to the *Journal* the Association publishes a number of specialist journals, *Abstracts of World Medicine*, and, from time to time, reports of special

subjects. In collaboration with the Pharmaceutical Society of Great Britain it compiles and publishes the *British National Formulary*. The Association also possesses one of the world's leading medical libraries. This contains 70,000 volumes, and 1,600 periodicals are received regularly. The library has a large lending and circulating service and members are entitled to use its service for obtaining references. There are reading-rooms for those who are able to call at B.M.A. House. The Association also maintains a large film library and an extensive range of films is available for local meetings. Lastly, the help of a highly skilled and experienced staff at Headquarters is available to members in connexion with the many problems which arise in practice.

The policy of the Association is determined by the Representative Body, which is composed of representatives from all the Divisions. The Council is the executive of the Representative Body and is responsible for the general management of the Association affairs. Its method of election ensures representation of all parts of the United Kingdom, of the medical branches of the Fighting Services, the Public Health Service, and the Overseas Branches. Most of the day-to-day work of the Association is carried out through a large number of standing and special committees. The Central Consultants and Specialists Committee (which also has a regional organization) acts with the Royal Colleges on all matters affecting hospital staffs. The General Medical Services Committee acts as executive of the Conference of Representatives of Local Medical Committees in all questions affecting general practice in the National Health Service. The Public Health Committee, which has a working agreement with the Society of Medical Officers of Health, deals with all matters relating to the Public Health Service. Other committees of the Association are concerned with private practice, ethical questions, and the encouragement of medical science and research, and there are also special committees which look after the interests of groups of members in varying specialties and also joint committees with other bodies for the consideration of matters of mutual interest.

The Association has important Branches in Australia and New Zealand and flourishing local units in many parts of the British Commonwealth. The Medical Associations of Canada, South Africa, India, and Ceylon are affiliated to the British Medical Association.

Society of Medical Officers of Health

The Society of Medical Officers of Health (Tavistock House South, Tavistock Square, London, W.C.1) is a body of medical officers engaged in public health work. It has branches and groups throughout Great Britain and Northern Ireland, New South Wales, Malaya, and, since 1957, East Africa, which meet regularly to discuss the medical and administrative aspects of preventive medicine. The council of the Society, representative of the branches and groups, is the governing body in respect of policy and finance. It examines all legislation concerned with the Ministries of Health, Housing and Local Government, Agriculture, Fisheries and Food, Education, the Home Office, and the Department of Health for Scotland, and with public health, and maintains relations with the public health departments of the universities and local government authorities. There is reciprocal representation on the Public Health Committee of the British Medical Association and the council of the Society, and the Public Health Committee acts in conformity with an agreement with the Society of Medical Officers of Health under which medico-political activities are undertaken by the Association.

The mental health group, inaugurated in March, 1957, continues to expand and to attract to it an increasing number of consultants in the mental health field. A recent development is the formation of a joint body comprised of equal numbers of members of the Royal Medico-Psychological Association and of the Society. This body will address itself in the first instance to considering common

problems in the care of the mentally disordered, with particular reference to the report of the Royal Commission on Mental Illness and Mental Deficiency. The teaching group, established at the same time, has concerned itself with the future of the medical services and its implications for the teaching of social medicine, with the content of social medicine teaching, both undergraduate and postgraduate, and with teaching methods. The Society is fully conscious of the need to keep members abreast of modern practice and developments in the field of public health. Accordingly, the various groups of the Society arrange refresher courses for their members, which are well attended. Courses are held by the county borough, county district, dental, maternity and child welfare, mental health, school health, and Services groups of the Society.

Medical Women's Federation

The Medical Women's Federation (Tavistock House North, London, W.C.1) works closely with the British Medical Association, and is represented by a woman member on the General Medical Services Committee. The Federation is the only professional organization consisting solely of medical women, and is thus in a position to represent the interests of women doctors and to deal with the problems affecting them as a minority in the profession. It also considers and investigates medical matters of special concern to women doctors. The Federation has active local associations all over the Kingdom, including a large London association, and an association of its overseas members. These associations meet regularly, and the *Journal* of the Federation is published quarterly for private circulation among its members.

British Medical Students' Association

This association was founded in 1942, and its membership now includes over 90% of the medical students in the country. It is purely a professional organization, providing a means of communication between medical students in the different universities and hospitals, and also between British students and those in other countries. It presents the medical students' point of view to the medical profession, to Government departments, and to other interested bodies. The organization of the association depends on an annual general meeting at which an executive committee is elected, and on four regional councils. Both clinical and preclinical conferences and "schools" are arranged from time to time, and these are appreciated not only for their academic interest but also for the opportunities which they provide for meeting fellow students from other medical schools. Local activities of the constituent organizations of the association include lectures, visits, discussions, and the showing of films from the B.M.A. and other film libraries. Amongst its publications are the *British Medical Students' Journal*, which appears once a term, and an annual list of vacation appointments for those members requiring work in hospitals during vacations.

The principal activity of the B.M.S.A. during the past three years has been the work of its medical education subcommittee. The subcommittee has prepared reports on entry to the medical course, the first year of medicine, the preclinical curriculum, and this year, as a result of a carefully conducted survey of the clinical curriculum, hopes to publish its views on the clinical section of the medical course. These reports are available to all who are interested in medical education, and the subcommittee is only too pleased to receive comment on the reports.

The association is represented on those committees of the B.M.A. that deal with matters affecting students and newly qualified doctors, and has recently taken an active interest in the formation of the new Junior Members Forum. The happy liaison with the College of General Practitioners has been continued, and the association's representatives sit on the undergraduate education committee of the College. Close interest is maintained in the British Student Tuberculosis Foundation and the United Kingdom Committee of

the World Health Organization. Active co-operation exists between the B.M.S.A. and other student organizations.

The B.M.S.A. is a founder member of the International Federation of Medical Student Associations, whose membership now embraces the associations of 21 nations. I.F.M.S.A. continues to develop successfully, and is recognized by the World Medical Association and Unesco. Under its auspices the annual students' international clinical conference has been held this year in Scandinavia. Opportunities also exist for individual clerkships in hospitals abroad, and the B.M.S.A., through the offices of a student international secretary, does much to assist British students to take advantage of these and other opportunities to travel and see something of medicine in other countries. Similarly, the B.M.S.A. makes arrangements for many foreign students to visit hospitals in this country. This year the number of students making use of these facilities has greatly increased. To encourage and assist deserving British students to attend courses and hospitals abroad the B.M.S.A. established four years ago a travel fund. This year the administrators of the fund awarded twenty-four scholarships of the total value of £200. It is hoped to improve on this figure in future years.

As its honorary president this year the B.M.S.A. has Sir Tudor Thomas, a past president of the B.M.A. The address of the association is B.M.A. House, Tavistock Square, London, W.C.1.

ADVISORY BUREAUX

Medical Practices Advisory Bureau

The National Health Service brought many changes in traditional methods of entering practice, and it was felt that there should be some advisory body which, though not directly linked to central or local government, could maintain effective liaison with executive councils, hospital management committees, the medical practices committee, etc., and at the same time command the confidence of the profession. To meet this need the Medical Practices Advisory Bureau was established in 1948 as a department of the British Medical Association under the direction of a medical member of its Secretariat.

The bureau has two functions; it acts as an agency and source of information concerning openings in various fields of practice, introducing partners, assistants, and locums. Secondly, it is prepared to advise on individual and personal problems associated with entry into and the day-to-day conduct of practice. For example, though it is not the function of the bureau to give legal advice, there are many questions concerning partnership agreements where the advice of an experienced doctor is needed as well as that of a lawyer. It is the accepted policy of the Association that there should be a legal agreement between principals and assistants in all cases, and the bureau can supply a model form for this purpose.

These services, which are available to all doctors, are, with very few exceptions, free of charge to members of the B.M.A. Others may be required to pay nominal charges for the agency services. Inquiries should be addressed to the medical director either at the Head Office of the Association in London or at the Branch Offices—33, Cross Street, Manchester 2; 7, Drumsheugh Gardens, Edinburgh 3; 9, Lynedoch Crescent, Glasgow C.3.

Commonwealth and International Medical Advisory Bureaux

The Council of the Association has set up at Headquarters, Tavistock Square, two bureaux, one of which welcomes doctors visiting this country from other parts of the British Commonwealth and provides them with a personal advisory service. The other serves a similar function for doctors from countries outside the Commonwealth.

The Commonwealth Medical Advisory Bureau invites doctors from overseas to write to its medical director (Dr. R. A. Pallister), preferably well in advance of their proposed visit, stating their expected date of arrival, whether accompanied by their family, how long they propose to stay, and in what ways assistance can be given. If an overseas doctor wishes to visit hospitals or seeks advice about postgraduate courses, he should add particulars of his professional experience. The medical director will also be pleased to see him at the bureau as soon as possible after his arrival or to talk over any points on which he may need advice or assistance. Contact is maintained with medical schools, postgraduate institutions, hospitals, and other bodies able to assist overseas visitors in the educational field. A register of suitable hotels and lodgings is maintained by the bureau, and general information is given on travel, customs duties, facilities for sport, exhibitions, and the like.

The other bureau is the International Medical Advisory Bureau, also located at B.M.A. House and also under the directorship of Dr. Pallister. Here again information is obtainable on postgraduate education, visits to hospitals and clinics are arranged, and assistance is given to visitors in finding accommodation and in other respects. The bureau also arranges holiday exchanges between the families of U.K. members and their Continental colleagues; last year nearly 200 such exchanges were arranged.

Medical Insurance Agency

The Medical Insurance Agency (B.M.A. House, Tavistock Square, London, W.C.1) is a recognized agent of all the leading insurance offices, and is thus able to obtain for members of the medical profession the best terms available in the insurance market. The Agency, which was established in 1907, distributes all its surplus to medical and dental charities. Special loan facilities are available for the purchase of houses, motor-cars, and equipment. Information can be obtained from the chief office of the Agency (Telephone No. : Euston 6031) or from its branches in Birmingham, Bristol, Cardiff, Dublin, Edinburgh, Glasgow, Leeds, Manchester, and Newcastle.

DEFENCE SOCIETIES

The *Medical Defence Union* (Tavistock House South, Tavistock Square, London, W.C.1) has a membership in excess of 45,000. The Union accepts medical and dental practitioners as members, whether practising in the United Kingdom or in certain countries overseas. A particular appeal for early membership is addressed to the provisionally registered practitioners when they commence their hospital duties. Special arrangements exist with regard to the protection of temporarily registered medical practitioners who visit the United Kingdom to obtain further experience or a higher qualification.

All members elected since October, 1953, pay their second and subsequent subscriptions on the anniversary date of their application for membership; members previously elected pay their subscriptions on January 1 in each year. The Union provides advice and full financial indemnity for any member concerned with, or involved in, medical litigation raising a question of professional principle or allegation of professional negligence. The subscription for newly qualified practitioners is £1 for the first three years, £2 for the fourth year, and £3 thereafter, with special rates for overseas practitioners. Since its foundation the Union has spent over £750,000 in the payment of damages and costs incurred in protecting its members.

The *Medical Protection Society* (Victory House, Leicester Square, London, W.C.2) has a membership of over 34,000. Membership is open to registered medical and dental prac-

tioners, including those provisionally registered. Members are afforded advice and assistance in all matters of professional difficulty, with unlimited indemnity against legal expenses incurred in defending and conducting cases on their behalf, also against costs and damages in those cases in which adverse verdicts result. Legal expenses and amounts paid by way of adverse costs and damages greatly increased during the past year. Indemnity is secured by financial resources of £220,000 and reinsurance with Lloyd's underwriters. There are special provisions for members practising overseas: practitioners throughout the Commonwealth are joining the Society in increasing numbers.

The *Medical and Dental Defence Union of Scotland* (105, St. Vincent Street, Glasgow, C.2) has a membership of approximately 8,500. The number of claims appears to be reasonably steady, but the amounts claimed show a tendency to increase. A number of claims have been defended successfully and the professional reputation of the doctors concerned completely vindicated in the Courts, sometimes at a cost to the Union running into thousands of pounds. It is very rarely that anything is recovered, as most of the claimants are suing with the help of Legal Aid.

NURSES AND MEDICAL AUXILIARIES

The General Nursing Council and the Royal College of Nursing

The differences in the respective responsibilities of the General Nursing Council and the Royal College of Nursing in the field of nursing education are not always understood.

The General Nursing Council is the statutory body responsible for the conduct of nursing education in hospitals approved as nurse-training schools for admission to the *Register of Nurses* or to the *Roll of Assistant Nurses*. The Council was, by the Nurses Registration Act, 1919, set up to form and maintain a *Register of Nurses*, subdivided into a general and special parts, and to lay down conditions of admission to it. Similarly in 1943 the Council was required by legislation to form and maintain the *Roll of Assistant Nurses*. Admission to the *Register* is by examination on completion of three years' hospital training, and among the functions exercised by the Council are the approval and inspection of training schools, the drawing up of syllabuses, and the appointing of Boards of Examiners. Admission to the *Roll* is on completion of two years' training in an approved training school under the supervision of State-registered nurses; the assessment conducted by the Council may be taken at any time after the completion of one year's training.

A further aspect of the Council's responsibility for basic nursing education is the adaptation of training to meet changing needs and conditions within the Health Service, as illustrated in recent years by approval given to experimental schemes for integrated training—for example, general and sick children, general and mental, general and public health nursing.

In Scotland a separate council has similar obligations to those of the General Nursing Council for England and Wales. In Northern Ireland the Joint Nurses and Midwives Council is the parallel body.

The Royal College of Nursing is an independent voluntary body founded by leaders of the nursing profession in 1916, before the attainment of State registration, which was one of its early objectives. Its activities, laid down in its Royal Charter, 1928, can be grouped under three headings: educational, professional, and welfare.

The educational programme of the College provides opportunities for State-registered nurses who have completed their basic training to undertake advanced study in preparation for administrative and teaching posts in hospital and public health work or for other senior positions. The

College believes it is essential for nurses who wish to take up higher appointments to be so prepared. Courses provided by the College include a two-year course in preparation for the Sister Tutor Diploma of the University of London and a course for the Health Visitor Certificate of the Royal Society of Health. The College also awards its own certificates on successful completion of courses given for nurse administrators and teachers, for ward and departmental sisters, and for occupational health nurses. Refresher courses and study conferences are also arranged.

The Scottish Board of the College and its Committee for Northern Ireland also arrange post-registration courses and the Birmingham Centre of Nursing Education provides refresher courses for students in that area.

The respective functions of the two bodies with major responsibility for nursing education was given in greater detail in the *British Medical Journal* of September 7, 1957 (p. 586).

Medical Auxiliaries

The *Board of Registration of Medical Auxiliaries* (B.M.A. House, Tavistock Square, London, W.C.1) exists to maintain and publish a register of properly qualified medical auxiliaries. The Board helps the medical auxiliary professions to attain or to consolidate and improve their professional status, and insists that each such profession shall, before registration, establish at least the basic principles for training and practice. In return it offers the registered persons protection in that they and they only are recommended to doctors as qualified to practise their particular specialty.

Separate or sectional registers of members of each branch of medical auxiliary work are printed, and are supplied free to medical officers of health, hospital management committees, hospitals, executive councils, public libraries, medical practitioners, and others, the circulation lists varying according to the particular group of auxiliaries.

The register is composed of the following sections: audiology technicians, chiropodists, dispensing opticians, operating theatre technicians, orthoptists, radiographers, and venereal disease technicians. Copies of any or all of the current sections will be sent free to medical practitioners on application to the registrar.

The *Chartered Society of Physiotherapy* (Tavistock House South, Tavistock Square, London, W.C.1) approves 34 schools, connected with hospitals in London and the Provinces. These schools prepare students for the Society's examinations, which are recognized by the Ministry of Health under the National Health Service (Medical Auxiliaries) Regulations, 1954. Successful candidates may practise as Chartered Physiotherapists.

The Trading Representations (Disabled Persons) Act received the Royal Assent on July 23. Its purpose is to control the attempts of certain traders to exploit the sympathy and good will which is generally felt for blind and other disabled people by making misleading and exaggerated claims about the extent to which their business provides employment for, or otherwise benefits, such people. It applies only to representations made in the course of postal or house-to-house canvassing, since it is these particular forms of trading which are thought to have given rise to abuse. The effect of the Act is that after January 1, 1959, it will be a punishable offence to make the kind of representations referred to in the Act unless the person carrying on the business has his name included in a register to be set up by the Minister of Labour and National Service. This provision will not apply where the business is carried on by a local authority, by a non-profit-making body, or by a disabled person selling his own products. Any person guilty of an offence under the Act will be liable on summary conviction to a fine not exceeding £100 or imprisonment for a term not exceeding three months, or both.

To-day's Drugs

In this column we publish from time to time authoritative notes on a selection of drugs in current use.

Codelprone (Merck Sharp and Dohme Ltd.).—Each tablet of this substance contains prednisolone 2 mg., meprobamate 200 mg., and dried aluminium hydroxide 200 mg. The rationale of this mixture is that the calming effect and spasmolytic action of meprobamate and the buffering action of the antacid are added to the anti-inflammatory action of the steroid. It is therefore put out for use in all those conditions for which prednisolone is at present prescribed; its indications and contraindications are those of prednisolone. The dosage recommended is the lowest which keeps the symptoms adequately controlled; an initial dosage of 2 tablets three or four times a day is suggested.

N.H.S. basic price: 100 tabs., 72s.

Bemaco (B. M. Laboratories Ltd.).—The composition of these tablets is: chloroquine phosphate 42 mg., acetylsalicylic acid 162.5 mg., calcium carbonate 45 mg., ascorbic acid 25 mg., and citric acid 15 mg. The rationale here is that the action of chloroquine potentiates that of acetylsalicylic acid, and for this reason its use is advocated in rheumatoid arthritis and allied arthropathies in a dose of 6 to 12 tablets a day. But chloroquine can hardly as yet be said to have been accepted by most clinicians as of proved use in rheumatoid arthritis.

N.H.S. basic price: 100 tabs., 10s.

Chloromycetin Palmitate Suspension (Parke, Davis and Co.).—Chloramphenicol (chloromycetin) palmitate has not the bitter taste of chloramphenicol. The palatability of this suspension thus enables the antibiotic to be given without difficulty to children who cannot swallow capsules. This compound is broken down in the bowel, and the chloramphenicol so liberated is absorbed, exerting the same action as if it had been administered as such.

Chloramphenicol is superior to any other antibiotic for the treatment of typhoid and paratyphoid fever and of severe cases of salmonella gastro-enteritis; for some forms of meningitis, particularly those due to coliform bacilli or *H. influenzae*, both because of the sensitivity of these species and because chloramphenicol attains higher concentrations in the cerebrospinal fluid than other antibiotics; and for infections of the air passages due to *H. influenzae*. It is also valuable, although its superiority to other drugs has perhaps not been so clearly proved, in acute laryngitis, tracheo-bronchitis, whooping-cough, and the virus pneumonias. As a broad-spectrum antibiotic it has many other possible uses for which other drugs are as good or better.

Whether this distinction between indications for which there are or are not equivalent alternatives is important depends on the view taken about the risk of producing aplasia of the bone marrow. The frequency of this complication is much disputed. A recent author reports 7 cases seen in one city within a year, while others have used the drug freely without ever encountering it. No second factor contributing to it is known. The risk is probably greater when large doses are given or treatment is prolonged. It is probably unwise to continue a course for much more than a week, but this should rarely be necessary.

N.H.S. basic price: 60 ml., 10s. 8d.

Correction.—We regret that the N.H.S. basic prices for "nilergex" tablets were given incorrectly (August 23, p. 507); they should be: 100 4-mg. tabs., 18s. 4d.; 100 12-mg. tabs., 33s. 4d.

Correspondence

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Human Mammotrophin

SIR.—At the Annual Meeting of the B.M.A. this year, during a plenary session of the Section of Surgery, Dr. A. C. Crooke opened a discussion on advanced carcinoma of the breast (*Journal*, July 26, p. 225). He emphasized the complexity of the hormonal factors controlling breast development, and, with every justification, warned his audience against uncritical interpretation of hormone assays in the human. He stated that I had claimed to have detected a mammatrophic hormone in human urine but that my results have been challenged and other workers have failed to confirm them. I should be grateful if I may be allowed to comment on this statement.

It has been assumed for several years, and with increasing conviction, that human female urine must contain, in small and probably minute quantities, a protein hormone of pituitary origin which in conjunction with ovarian steroids controls the proliferation by mitosis of mammary epithelium and is thereby responsible for the production of a duct system. In 1955, Dr. E. F. Scowen¹ suggested that it should be possible to detect such a hormone by injecting a urinary extract containing an adequate proportion of normal urinary extract into weanling male mice. These animals were suggested because the high growth potential of their rudimentary mammae enables them to be rapidly feminized by specific exogenous stimulation and their simplicity of structure provides an ideal zero baseline for the detection and estimation of an artificially induced growth response. The proposal was then subjected to experimental test and an unmistakable growth response was induced in the mammae of weanling male mice of a commercial strain by injecting a Klinefelter extract of the urine of a normal pre-menopausal woman.²

During the next year this initial and successful experiment was repeated on a large scale, again using commercial mice but omitting the Klinefelter extraction as being untrustworthy. The finding of a large number of urines from healthy women was shown to induce an unequivocal mammary growth response in weanling male mice.³ We were then compelled to discontinue the use of commercial mice because of serious, frequent, and unmanageable irregularities in their mammary reactivity. A reactive pedigree strain (Strong A2G) was then discovered. One breeding colony of this strain is maintained under strict genetic control in our own laboratories. Two other colonies are kept under similar conditions—one at the Laboratory Animals Centre of the Medical Research Council and the second at the Imperial Cancer Research Fund's laboratories at Mill Hill. We are fully convinced that the above precautions are essential if accurate and consistent results are to be obtained by the use of intact mice.

Some time ago, in reviewing our problems, we decided that an accurate bioassay of human mammatrophin calls for a far more rigorous quantitative method of extracting urine protein than the simple procedures we had at first employed. This problem is being investigated but is still unsolved. We were also disturbed by the lack of any rigid proof that the mammatrophic responses observed in our mice injected with human urine were induced by a pituitary hormone of human origin. It is becoming increasingly difficult to deny that one of the major functions of the oestrogenic ovarian steroids is to release mammatrophic hormones from the anterior pituitary by selective stimulation of its mammatrophic cells. It was therefore difficult to escape the probability that if an injected urine contains oestrogens, even in very small amounts, enough mammatrophin will be released from the mouse pituitary to induce mammary growth. In the face of these doubts and difficulties we decided to use totally hypophysectomized mice and to discontinue the use of intact animals. This removed many of our difficulties. It has provided good evidence that the mammatrophic agent in human urine is an anterior pituitary hormone of human origin and in other respects it has proved to be a sensitive test object for the investigation of pituitary function.

We are not surprised that other observers have failed to reproduce our initial results in intact mice. We now consider the investigation of human pituitary function in the intact animal to be fallacious and confusing. To the best of our knowledge the work we have done on hypophysectomized animals has not been repeated.

Dr. Crooke suggested that our results may be important and should be confirmed. We are encouraged to hear this, but we hope that those who may embark on this problem will use totally hypophysectomized weanling males of a reactive and carefully bred strain. The total removal of the anterior pituitary in a 10-gramme mouse is a far less lethal and formidable operation than is generally supposed. One trained operator can easily provide 80 totally hypophysectomized weanlings a week.—I am, etc.,

Anorexia Nervosa

SIR.—As one of us (W. S.) was, in 1951, one of the first to report the use of modified leucotomy in the treatment of anorexia nervosa, we are interested to see that Dr. E. Williams (*Journal*, July 26, p. 190) still recommends the use of this treatment as the alternative to intubation when all else has failed. However, we hope that it may now be generally possible to avoid modified leucotomy, since we have been very impressed with the effects of combining large doses of chlorpromazine with a modified insulin regime, provided the patient is confined strictly to bed. We have given our patients up to 1,000 mg. of chlorpromazine in the 24 hours (the average dose being about 600 mg.) and insulin in doses of around 60–80 units; the dose of chlorpromazine is, however, reduced when they are allowed up again. No undesirable complications have occurred so far in 11 patients who conform closely to Gull's original description of anorexia nervosa. We stumbled upon this combination accidentally, after we had learned about the possible value of reserpine and chlorpromazine in anorexia nervosa. But we are not very impressed with the use of either of these drugs alone, and reserpine can make patients very depressed.

For many years now one has tried to use modified insulin alone, but it has seemed to us to have been singularly unsuccessful in most patients, despite the hunger-producing effects of the insulin regime. The effect of adding chlorpromazine to the insulin seems to break down the patient's previous ability to go on refusing food. Dr. D. Stafford Clark (*Journal*, August 16, p. 446) stresses the long time needed to restore weight in anorexia nervosa under an ordinary hospital regime, combined with psychotherapy. The average duration of each admission in his series of 13 was about 3½ months, and the average weight gain during this time was 22 lb. (10 kg.). We have found that an average of 4.2 lb. (1.9 kg.) a week was gained by our 11 patients with their combined treatment, their average stay in hospital being 32 days. One patient, for instance, gained 32 lb. (14.5 kg.) in 56 days, and another 25 lb. (11.3 kg.) in 27 days, the lowest in the series gaining only 11 lb. (4.9 kg.) in 19 days before taking her discharge against advice. We have rarely seen such rapid restorations of physique in anorexia nervosa as we have recently been obtaining with this combination of treatments skilfully applied, but no doubt we shall also meet with more failures later on.

We have found psychotherapy to be generally unnecessary during the initial phase of the recovery of lost weight. But the general handling of the patient has to be sensible and firm, and the patient must be supervised and left in no doubt that she will not be allowed out of bed until the desired gain in weight has occurred. Before the advent of combined insulin and chlorpromazine treatments this firmness

and supervision alone frequently failed. Psychotherapy and support does, however, seem necessary in addition to maintenance doses of chlorpromazine in the follow-up stage in order to prevent relapse when the patient has to return to conditions which may have helped to bring about or precipitate the illness. We have not found that the use of chlorpromazine alone can prevent relapse after discharge. Our longest follow-up is now three years, and so far there have been two bad relapses in those who had initially done very well; one of these has responded to a further course of combined treatment.

We hope to report our findings in greater detail later on if they continue to prove worth while, but meanwhile there may be other patients who might benefit like ours from this new combined method, about which we have so far found no reference in the literature. We also feel with Dr. Stafford Clark that intubation is most undesirable, and that this illness is full of psychological components in the total picture.—We are, etc.,

Suckling in Infants

SIR,—We were interested in the recent paper by Drs. J. R. T. Colley and B. Creamer (*Journal*, August 16, p. 422) describing the pressures measured in the mouth during the bottle-feeding of babies. Our own paper correlating pressure measurements during bottle- and breast-feeding with simultaneous cineradiography is awaiting publication. Under the conditions which Drs. Colley and Creamer describe in their paper, the pressures they record are exactly as we would expect. They have used their findings to criticize our description of a squeezing action of the tongue upon the bulb of the teat, despite the fact that we clearly stated that, unless the lumen of the neck of the teat was occluded or very much narrowed, the squeezing action of the tongue was ineffective.¹ We also stated that it was rare for the baby to be able to occlude the neck and to express the contents of the usual type of commercially made teat sold in this country; the type of teat which Drs. Colley and Creamer used is advertised as being constructed so as to prevent collapse of the teat.

If a soft rubber teat is used, which permits the neck to be occluded and which the tongue may indent, there is a significant rise in pressure within the lumen of the teat. Kid-goats and calves, when feeding from their mother's teats, also obliterate the lumen of the teat sinus from above downwards, causing a rise of pressure within the lumen of the sinus comparable to that obtained inside a soft rubber teat.^{2,3} We have also shown that the appearances of the teat sinus when milked by a standard intermittent negative-pressure milking-machine are not comparable.⁴ In our first paper¹ we were very careful not to forecast the relative magnitude of the positive- and negative-pressure elements until we had made pressure measurements, but we did point out that, when using a soft teat, the amount of milk obtained during the phase when the lumen of the teat was obliterated by the tongue was roughly equivalent to the amount which flowed into the back of the mouth beyond the end of the teat prior to the initiation of this phase: we suggested how suction might be created.

The statement by Drs. Colley and Creamer that suction is produced by a backward movement of the tongue within the mouth is not quite correct. The idea that suction was created by the lowering of the tongue from the roof of the mouth from before backwards was put forward by Auerbach⁵ in 1888. As we have shown,^{1,6} it is this movement which assists in refilling the teat and which may cause milk to flow into the back of the mouth: but this action alone can never empty the teat. Emptying of the teat is associated with elevation of the tongue to the palate from

before backwards, and simultaneously there is lowering and forward movement of the back of the tongue, thus continuing to create suction; it is the latter movement which makes the cavity in which the milk accumulates prior to swallowing.

For successful bottle-feeding with commercial teats of the type sold at the present time, the size of the hole in the teat is the most important factor. If the hole is big enough, fluid flows through it into the mouth cavity and the associated pressure gradient between the lumen of the teat and the cavity of the mouth is relatively low. But, if the hole is small, very little milk may be obtained, even though a very steep pressure gradient is created.—We are, etc.,

SIR,—I was interested to read of the experiments carried out by Drs. J. R. T. Colley and B. Creamer (*Journal*, August 16, p. 422) to record intraluminal pressures of the oesophagus and pharynx, the mouth and teat, in bottle-feeding. The findings need careful study and will add to our knowledge of a subject which has so often been taken for granted.

When working with the late Professor James Whillis, in the department of anatomy, Guy's, on the evolutionary history of the orofacial muscles in relation to breathing, feeding, and dental arch form, cine films of bottle-feeding were made which confirm the observations of Ardran and Kemp.¹ Moreover, it seemed clear to us from the revealing monograph on sucking by Auerbach,² and from our records, that sucking should not be confused with suckling. They are not synonymous terms. In sucking, the lips need to be sealed effectively round the opening of the vessel containing the fluid. Auerbach described a sucking space in the mouth which is formed by lowering the jaw and depressing the anterior half of the tongue away from the hard palate whilst keeping the posterior half heaped up in apposition with a tensed soft palate. A resultant intraoral negative pressure allows this space to be filled with fluid which can then be swallowed.

In suckling, the lips envelop and support the teat but an airtight seal is not necessary. The suckling process is brought about by a rhythmical furrowing and bulging action of the tongue in peristaltic fashion to pump and squirt the milk into the pharynx. A slow-motion cine film was made of an infant with bilateral hare lip and cleft through the upper alveolus but not through the palate. No intraoral negative pressure was possible. Suckling movements once started would continue for a few seconds when the teat was removed from the mouth. We were thus able to record the suckling cycle, obtaining a view of the oral cavity as far back as the soft palate. First, the jaw was lowered and a central grooving of the tongue allowed milk to flow into the teat. Then a sharp upward impinging of the blunt anterior margin of the tongue was followed by an elevation of the lower gum pad to nip the neck of the teat against the everted premaxilla (or upper gum pad had it been intact). This prevented the return flow of milk into the bottle while the teat was rolled out against the hard palate by a progressive bulging of the tongue from before backwards to express the milk. The central bulging of the tongue posteriorly against a tensed soft palate seemed to squirt the milk past the faucial margins in an almost continuous stream into the lateral food passages of the pharynx. How much milk was actually swallowed rather than squirted directly into the pharynx is not easy to say. There was no interference with the rhythm of breathing, and from studies in comparative anatomy I favour the latter method of transference as predominant. There was no backward movement of the tongue which could be likened to the action of a piston in an airtight syringe.

Innate patterns of muscle behaviour essential to life are stereotyped and common to all members of the species. I believe that the above pattern of muscle activity is primarily responsible for the suckling act and varies, not in form, but in degree from infant to infant, or in the same infant at different times; that intraoral negative pressures are to

be expected; that they are incidental yet helpful to the infant in suckling. I fully support the cineradiographic findings of Ardran and Kemp.—I am, etc.,

E. GWYNNE-EVANS.

Cow's Milk Allergy

SIR,—I read with great interest the article by Drs. B. D. Bower, D. G. Stanley-Roose, and O. H. Wolff (*Journal*, July 26, p. 195) entitled "Two Cases of Cow's Milk Allergy." I practise in a rural dispensary district in Co. Kerry, Ireland, and in the past four years I have come across six cases of cow's milk allergy in infants.

The following is a brief description of two of those cases.

Case 1.—I first saw this bottle-fed infant when she was 14 weeks old. The mother stated that she had been restless, vomiting, and refusing feeds for about four days. The child's general condition was very good. A roughness of the skin on the forehead was noticeable, and an erythematous rash was apparent on the chest and trunk. The family history was that the father had suffered from nasal catarrh, and that the paternal mother had had bronchial asthma all her life.

Treatment was as follows. Milk for feeds was prepared by adding, drop by drop, slowly stirring to avoid curdling, a mixture of 40 minims (2.3 ml.) of dilute hydrochloric acid (B.P.) in 2 drams (7 ml.) of water to one pint (0.6 litre) of cow's milk which had previously been boiled for 10 minutes. To prevent scratching, an ointment was applied consisting of a solution of coal tar dr. 1 (3.5 ml.); zinc oxide dr. 2 (7.8 g.); powdered starch dr. 2 (7.8 g.); soft paraffin dr. 1 (3.5 ml.).

Case 2.—This child was also a bottle-fed infant 18 months old. She had a widespread weeping eczematous condition on the face, chest, trunk, and limbs. The rash first appeared at the age of 3 months. It began on the forehead, and gradually spread over the face, chest, and trunk until the whole body was covered. In spite of this the child's general condition was good. The child's uncle suffered from asthma. The same treatment was prescribed as in the previous case, and in ten days there was a marked improvement. The weeping condition of the skin had completely disappeared, the irritation was not present and the child was now sleeping very well. The acid-milk treatment was continued for five months, and after that the child took untreated cow's milk without any ill effects.

The remaining four cases received the same treatment, and all responded excellently.—I am, etc.,

Co. Kerry.

REDMOND M. O'BEIRNE.

Intracellular Iron-containing Enzymes

SIR,—Your excellent leading article on iron stores and iron deficiency (*Journal*, May 17, p. 1167), prompts me to draw the attention of your readers to the mounting evidence that basic disorders of intracellular iron-containing enzymes and perhaps resulting cellular anoxia may underlie various anaemias, on the one hand, and haemochromatosis as well as nutritional siderosis in Africans on the other. Your leading article makes only limited reference to related literature on this aspect of these problems. Since the altered iron absorption and utilization in all the above conditions may perhaps be only secondary to primary lesion(s) of the intracellular iron-containing enzymes, further reference to relevant data seems timely.

The nature of the prevailing intercellular metabolism probably exerts a profound influence on the uptake and utilization of iron by any cell. This is supported (perhaps so diagrammatically as to go unnoticed in the present context) even by the unique capacity of red cell precursors to take up iron, this capacity apparently diminishing as these cells mature.¹ It is not surprising, therefore, that in anaemias iron metabolism is deranged in varying degrees in many cells in the body other than those concerned with erythropoiesis. The findings of Beutler,² quoted in your leading article, are indeed satisfying proofs of this. However, the presence of widespread cellular metabolic derangements in the presence of widespread cellular metabolic derangements in anaemic subjects is evinced also by the now generally recognized

epithelial siderosis (see below) and megalocytosis even in non-haemopoietic cells in pernicious anaemia.^{3,4}

That bodily iron uptake and utilization may be profoundly altered by anoxia is supported by several recent studies. Thus, Smith *et al.*⁵ revealed that rats exposed to low oxygen tensions for as little as two hours absorbed far greater amounts of a single-standard test-dose of radio-iron than their controls at ambient oxygen tension. These workers suggested that their results indicated "that iron absorption from the gastrointestinal tract is a dynamic cellular process and not a matter of simple diffusion," a view favoured also by Granick⁶ and others. Additional evidence, substantiating the effects of anoxia on cellular enzyme composition, was provided by Tappan *et al.*,^{7,8} who demonstrated increased concentrations of certain oxidative and non-oxidative cellular enzymes as well as increases in skeletal muscle myoglobin in animals acclimatized to high altitudes. The repercussions of these enzyme increases on iron metabolism were not studied by these authors, but the work of Smith *et al.*, mentioned above, indicates the probable trends. Moreover, Colehour and associates^{9,10} demonstrated that even acute hypoxia induced an almost immediate rise in transferrin and a fall in serum iron, while Prentice and Mirand¹¹ found an increased circulating erythropoietin for up to five days following acute hypoxia, this increase being maintained for much longer periods in rats with previously injured livers. Such increases in erythropoietin which occur also in anaemias may perhaps play a part in promoting increased iron uptake from the alimentary tract. This possibility is strongly supported by the recent demonstration of two- to sevenfold increase in iron uptake by bone marrow cells exposed *in vitro* to "erythropoietin."¹² Thus, acute hypoxia can promote, probably through several mechanisms (direct and indirect) an increased iron uptake by the gastrointestinal mucosal cells and also, perhaps, by many other cells in the body as a result of the associated alterations of intracellular metabolism.

We have repeatedly expressed the opinion that iron overload alone is not the cause of experimental siderosis. Our recent investigations¹³ disclosed that, in certain diets, iron uptake may not be a function of the iron intake alone. Thus, rats fed an iron-enriched maize-meal diet absorbed and accumulated almost three times as much body iron and twice as much hepatic iron as rats on an iron-enriched stock diet, even though the total daily intake of iron by the maize-eaters was far less (almost half that of the better-fed rats). There is some indication that some metabolic disorder, resulting in cellular anoxia, occurs at least in the livers both of pellagrins¹⁴ and of rats fed a maize-meal diet.¹⁵ Moreover, preliminary results of new experiments by us indicate that one hour's exposure to simulated high altitudes thrice weekly seems to intensify considerably the hepatic siderosis in rats fed iron-enriched maize but not in those fed an iron-enriched stock diet—both diets with equal calcium and phosphorus contents. The latter findings suggest that the "malnutrition" and intermittent decompression operate synergistically in facilitating the absorption and storage of iron in the liver—perhaps through a mechanism similar to that described by Prentice and Mirand and by Jacobson and co-workers.^{16,17}

Sheldon¹⁸ suggested that the intra-epithelial iron in idiopathic haemochromatosis was derived from the affected cells themselves, as a result of some genetically determined distortion of cellular metabolism. There are already indications that the increased intracellular deposition of copper in Wilson's disease is attributable to some congenital derangement in protein metabolism with consequent formation of an abnormal protein with an undue affinity for copper. It seems possible that an analogous lesion may underlie haemochromatosis, the increased absorption and accumulation of iron being in fact secondary. A similar explanation may also perhaps apply to nutritional siderosis in Union Africans—in this case the intracellular metabolic disorder perhaps resulting from long-term chronic malnutrition. Thus, even in 1944 it was shown that in nutritional siderosis iron accumulates first on or around the hepatic cell mitochondria,¹⁹ and the name "cyto-siderin" was proposed for this pigment in order to indicate its derivation from cellular enzymes rather than from haemoglobin. This observation has apparently been confirmed by Richter's recent electron microscope study,²⁰ quoted in your leading article. It is notable, too, that, in experimental siderosis in rats, iron also accumulates first along the biliary poles of the hepatic epithelium in a manner directly comparable with that described in the early stages of human siderosis.²⁰

It seems possible that the microcytic anaemias, so common among malnourished peoples, may also be secondary to intracellular metabolic disorders, produced by the inadequate diet, rather than simply to deficiency in iron intake alone. This seems all the more likely in view of Foy and Kondi's recent finding,^{21,22} based on extensive studies, that there is no evidence for a deficient iron intake by peoples with microcytic anaemias studied by them.

AITOLIA ENGLISH.

Zoster Sine Herpete

SIR,—Dr. G. W. Lewis's comprehensive and important article on zoster sine herpete (*Journal*, August 16, p. 418) prompts me to record two out of a number of cases in support of his contention that this is a commoner condition than has been realized.

During an epidemic of varicella in the late spring of this year a married woman of 35 years was awakened in the early hours with severe nausea and vertigo. She staggered to a wash-basin, but did not vomit. The attack passed off within the hour and next day the symptoms did not reappear, though she felt lethargic. The following night the episode was repeated and it was with difficulty that her husband got her back to bed, so severe was the vertigo. The next day mild nausea and a very slight vertigo were present during the day and she developed a fairly severe right otalgia. The drum was normal; she had no deafness, nor tinnitus. A coarse nystagmus could be elicited. The otalgia slowly diminished, lasting five days altogether. The nausea and vertigo disappeared after ten days. On the fourth day after the start of the otalgia, two small vesicles of herpetic type appeared above the right pinna.

The second case had a moral attached. A medical student was "sitting in" with me at a consultation period. I had said how important it was to examine fully any cases where examination might be helpful, when a woman came in with a history of sudden severe pain of sciatic distribution after moving a piano. I sent her to the examination room with instructions to disrobe from the waist downwards. When we came to her she had omitted to remove her stockings. On my request she removed them with ill grace and an "Is-it-really-necessary?" expression. To our surprise and my delight we saw a group of herpetic vesicles on the outer side of the great toe extending on to the nearby dorsum of the foot. She had no further outcrop and the diagnosis might easily have been missed.

These two cases are not "sine herpete" but "cum herpete minimo," and show that zoster may produce so few vesicles that they may be overlooked.—I am, etc.,

Leeds, 8.

R. A. MURRAY SCOTT.

Jack Sprat

SIR,—Dr. S. Levin's suggestion about the possible metabolic background to the dietetic difficulties of Mr. Sprat (*Journal*, August 23, p. 503) is certainly original; unfortunately he says nothing about Mrs. Sprat's troubles. Be this as it may, it may interest people to know that according to my family tradition in Norfolk Mr. and Mrs. Jack Sprat were real people; they lived at Hethersett, a village just south of Norwich, in the early part of the eighteenth century. That knowledge of the Sprats became widely known is easy to understand when it is remembered that Hethersett was on the old road from Norwich to London via Braintree, a busy route originally popularized by the silk merchants.

It is curious to reflect that, while most nursery rhymes have a factual origin and perpetuate important events in our national life, no additions to the collection seem to have been made for a couple of hundred years or so.—I am, etc.,

London, W.1.

W. R. THROWER.

Informing the Hospital

SIR,—Very often patients come into hospital with boxes of tablets, which they say their G.P.s have been giving them for a long time, the name of which is unknown to them. This means that the house-physician or house-surgeon has to find out from the G.P. the name of the drug, and this is time-consuming and also results in delay in treating the patient. Sometimes patients describe the colour or taste of a drug which they say they have been taking, and if something different is given to them quite often they grumble, and it produces a difficult situation between the outside practitioner and the hospital resident doctor.

I think it would be a better arrangement if the private practitioner could inform the hospital doctor of the chronic illnesses of the patients they send in with some different acute condition—for example, appendicitis with chronic heart failure or epilepsy, or disseminated sclerosis—and the

treatment they are on. The house-physician or house-surgeon always has to make his own diagnosis about the present ailment, but it is humanly impossible for him to find out the name of the tablets patients have been on previously or to make a correct judgment about their past illness, which may be of great value in the treatment of the present condition—especially where anaesthesia and operative measures have to be considered.

Therefore I would like, through your *Journal*, to urge that in future G.P.s should inform hospital practitioners about the past history of their patients and the treatment they are on, and I am sure this would be a great help for the inexperienced junior members of the medical world like myself.—I am, etc.,

St. Albans, Herts.

BISWARUP BHATTACHARYA.

Coudé Catheter

SIR,—The scene is a surgical ward of the London Hospital in the early twenties. Russell Howard is taking a teaching round, and is on the warpath.

RUSSELL HOWARD: "What is the name of this catheter, you?"

STUDENT: "A coudé, Sir."

RUSSELL HOWARD: "Why is it called coudé?"

STUDENT: "After a French surgeon, Sir."

RUSSELL HOWARD (with the well-known leer): "Yes, and I suppose his brother Bi Coudé invented the other one." Collapse of student.

Mr. Hamilton Bailey (*Journal*, August 23, p. 513) must have missed this particular round.—I am, etc.,

London, S.E.10.

STEPHEN POWER.

SIR,—When I was a medical student in Johannesburg thirty years ago the following anecdote was currently popular. The scene was an oral examination in surgery.

EXAMINER: "And what, Mr. Blank, is this?"

CANDIDATE: "A coudé catheter, Sir."

EXAMINER: "And why, Mr. Blank, is it so called?"

CANDIDATE: "After the eminent French surgeon M. Coudé, Sir."

EXAMINER (producing a second instrument): "And this one, I presume, Mr. Blank, after the even more distinguished French surgeon, M. Bicoudé?"

What a lot of red faces there ought to be about! But what a brilliantly successful leg-haul!—I am, etc.,

Devonport.

C. H. JOYNT.

POINTS FROM LETTERS**Radiation and Childhood Malignancies**

Dr. JOHN D. ABBATT (Meopham Green, Kent) writes: Your leading article on this subject (*Journal*, July 12, p. 96) was lengthy and uninformative. In this article you rightly say that the full results of the Oxford investigation¹ have been awaited with special interest; this is self-evident in view of the anxiety aroused by the initial report. In your leader, apart from recapitulating some of the more important radiological features in the report, little else was said. No editorial assessment of the value of the investigations nor of the practical significance of the findings was attempted. This is particularly unhelpful. Your very understandable desire to avoid being wrong has, I believe, led you in this instance and on this topic to publish a masterpiece of "fence squatting."

REFERENCE

Treatment of Boils

Dr. ALLENE SCOTT (London) writes: Allow me to say that I agree entirely with Dr. G. N. Marsh (*Journal*, August 16, p. 451) that treatment with expensive antibiotics is not routinely indicated for boils. As our observations showed (*Journal*, July 12, p. 83), minor grades of boil are unaffected, and, as Dr. Marsh says, penicillin is likely to be effective for the majority of more severe ones. We chose this type of staphylococcal infection for a therapeutic study only because plenty of cases are available and the progress of the lesion can be closely watched, in the hope that the lessons learned might be applicable in other directions.

Obituary

C. C. UNGLEY, M.D., F.R.C.P.

Dr. C. C. Ungley, physician to the Royal Victoria Infirmary, Newcastle upon Tyne, and well known for his work on the treatment of pernicious anaemia and subacute combined degeneration of the cord, died at his home in Newcastle on August 21. He was 56.

Charles Cady Ungley was born on July 14, 1902. At the University of Durham, where he studied medicine, he soon made his mark as a man who would distinguish himself in his chosen profession. Winning the Turnbull and Tulloch, Gibb, Dickenson, and Philipson scholarships, he graduated M.B., B.S., with honours, in 1925, and proceeded M.D. two years later. After resident posts at the Royal Victoria Infirmary he took the M.R.C.P. and was appointed medical registrar at the Infirmary in 1928.

At that time he was particularly interested in neurology, and his first paper on subacute combined degeneration was published in *Brain* in 1929. Soon afterwards he was awarded a Rockefeller medical fellowship and he became research fellow in medicine at Harvard University and at the Massachusetts General Hospital, Boston. By this time he had turned his attention to the treatment of pernicious anaemia and published several papers on the subject in the *Quarterly Journal of Medicine*. Having returned to Newcastle he was appointed assistant physician at the Royal Victoria Infirmary in 1935 and full physician in 1947. Elected a Fellow of the Royal College of Physicians in 1937, he was previously a Leverhulme research scholar of the College, and in 1938 he gave the Goulstonian Lecture on "Some Deficiencies of Nutrition and their Relation to Disease."

Ungley was no cloistered research worker, but a clinician interested in all aspects of medicine. For several years he was honorary secretary of the Newcastle and Northern Counties Medical Society, and he was a member of the R.N.V.R. from the time he qualified. During the second world war he served as a surgeon commander and did some notable work to improve the chances of survival of the shipwrecked. After the war he and his colleagues continued to make many valuable contributions to clinical haematology, several of his papers being published in this *Journal*.

Dr. Ungley is survived by his wife, one son, and two daughters. Professor F. J. NATTRASS and Dr. R. B. THOMPSON write: The death of Charles Ungley removes a distinguished figure from British medicine. Though he was working to the last he had been dogged by ill-health intermittently for the past fifteen years. This first appeared when he was stationed in the South Africa during the war as a medical officer in the Royal Navy, an acute infection leading to the discovery of marked hypertension. From time to time since then his work has been interrupted by symptoms related directly or indirectly to this condition.

Ungley's very active life divides itself naturally into three periods—before, during, and after the second world war. His first and still perhaps most important work was on subacute combined degeneration of the spinal cord, and was carried out initially in conjunction with M. M. Suzman. It was thought at first that Minot and Murphy's discovery of

the liver treatment of pernicious anaemia was not applicable to the associated nervous disorder, but these workers showed that with greatly increased doses of whole liver the disease could frequently be cured or arrested. To show this Ungley and his colleague examined and followed up virtually all the cases of subacute combined degeneration in the north-east of England, carrying out the work with scrupulous clinical accuracy. The tremendous advances which have followed the discovery of the liver treatment have not solved the fundamental problem of the relationship of the blood and spinal-cord changes. But this discovery was the main stimulus of modern haematology, and to continuing research in this field Ungley devoted the rest of his life in conjunction with general clinical work and teaching. When Castle put forward his hypothesis Ungley became greatly interested in the nature of the "extrinsic factor" and carried out much experimental work on this subject. He was also intrigued by the haematopoietic responses, which could be obtained by yeast extracts, and carried out many clinical trials with such preparations. This early work deserves very great credit, for it was done in scanty accommodation and with few facilities.

A keen member of the R.N.V.R., Ungley was called up for service and in due course was stationed at the Royal Naval Hospital at Kingseat, near Aberdeen. His energy and initiative quickly directed his attention to urgent Service problems, and his work in two directions was of a character undoubtedly historic—namely, on survival at sea of shipwrecked men and on the particular problem of such men which he named "immersion foot." Though, owing to his health, publication of his work on the general problems of survival was long delayed, his official report, in conjunction with McCance, Crosfill, and Widdowson, is of first-class importance. One contemporary problem with which it deals decisively is the grave danger of the drinking of sea-water. The distressing "immersion foot" he studied in detail, investigating its circulatory and neurological manifestations, its management, and its aetiology, including its differences from frost-bite and other conditions.

The post-war period found him at work again among the complexities of research on pernicious anaemia. One of the most rewarding of his investigations was a series of clinical trials which were carried out with purified liver extracts prepared by Lester Smith and his colleagues of the Glaxo Laboratories. This time-consuming method was the only one then available for assaying the potency of haematopoietic material. These trials helped very substantially towards the purification of liver extracts and the eventual crystallization of vitamin B₁₂. He was also very much concerned during this period with experimental work on the nature of "intrinsic factor." His interests, however, were not limited to investigation of classical pernicious anaemia, for he wrote many papers on related megaloblastic anaemias such as pernicious anaemia of pregnancy and anaemias associated with disease of the small intestine.

Ungley's work showed well the indivisibility of medicine, for he was as good a neurologist as haematologist and also taught and practised effectively in other branches of medicine. He was very keen on undergraduate teaching and was never happier than when teaching the elements of the art in the wards. He was the first physician in his hospital to arrange—irregularly!—for his clinical clerks to obtain periods of experience in general practice, and he picked the doctors carefully. When the National Health Service came in he chose a whole-time contract in order to give all his time to hospital and research, but formerly he was in consulting practice.

Ungley's knowledge of nutritional disorders and of pernicious anaemia was extraordinarily extensive and was always at the disposal of anyone interested in such problems. He did not find writing easy, and his many lucid scientific papers were produced only after very critical assessment of his results and with much labour. Perhaps his only intellectual hobby was medicine, but he enjoyed golf and rather alarmingly in his latter years became an expert glider. He

enjoyed wonderful holidays with his wife, son, and two daughters. He was a very modest man. He had complete integrity, great kindness, and charitableness to all.

Dr. E. LESTER SMITH writes: The importance of Ungley's pioneer work with vitamin B₁₂ has tended to be overshadowed by later exciting developments. It is no exaggeration to say that without his help vitamin B₁₂ would not have been isolated by the British team. Although pink concentrates were obtained in 1946, it was believed for some time longer that the colour was due to an adventitious pigment accompanying the active principle. It needed a total of some 80 clinical tests (many of them repeats on the same sample) before the relationship between colour and activity became firmly established, and nearly all these tests were carried out by Dr. Ungley personally. This work was never published in detail; for as soon as the crystalline vitamin became available Ungley devoted all his abounding energy to constructing dose-response relationship for pernicious anaemia cases with different initial red-cell counts, with and without neurological complications. He also tried all possible methods of administration and was the first to demonstrate dramatic remissions with single massive oral doses (3,000 micrograms). Ungley was also one of the first to insist that in the treatment of pernicious anaemia dosage schedules need no longer be restricted to those established for liver extracts, and to recommend the larger doses that have since become routine. He deserves greatly to be remembered for all this original work and for the several excellent reviews of the subject that he compiled.

Dr. ANDREW SMITH writes: Some mention should be made of Dr. Ungley's interest in teaching students and particularly in introducing them to general practice. He started a student-general-practitioner attachment scheme in King's in 1952, long before such schemes became general. He approached four general practitioners (of which I was one) with urban, semi-urban, rural, and small-town practices respectively and persuaded each to take a student for one day each week and show him something of general practice. This scheme differed from most others which have been introduced since in that the student saw different types of practice and different doctors, and he saw general practice at the beginning of his hospital career. This made him realize that patients are people with homes and families, not merely vehicles of disease, and coloured his subsequent dealings with patients in hospital. The scheme, started as an experiment over six years ago, has continued ever since.

A. MARION HILLIARD, M.D.

Dr. Marion Hilliard, who was well known as a specialist in obstetrics and gynaecology in Toronto and was a vice-president of the Medical Women's International Association, died on July 15.

Anna Marion Hilliard was born in 1902 at Morrisburg, Ontario, the third of a family of five, and was educated at Victoria College, Toronto, and at the University of Toronto, graduating M.D. in 1927. As a student she distinguished herself not only scholastically but also as an athlete. After spending a year in hospitals in London, including the Hospital for Women, Soho, she returned to Toronto, where she established herself as an obstetrician and gynaecologist. She played an important part in the development of the Women's College Hospital in Toronto from a cottage hospital of 75 beds to a modern hospital and teaching unit of the university with 500 beds. A past president of the Canadian Federation of Medical Women and a vice-president of the Medical Women's International Association, Dr. Hilliard was nominated shortly before her death for the office of president of the latter association. She gave up her appointment at the Women's College Hospital only last year, but had planned to continue in private practice for some time to come; and she was looking forward to the opportunities which presidency of the M.W.I.A. would afford her to study conditions in other countries, particularly in India. Generous

and warm-hearted by nature, she had provided funds to establish a student scholarship at the Victoria College in memory of her father, and she gave the proceeds from the sale of her book, *A Woman Doctor Looks at Love and Life*, to the Women's College Hospital. By Dr. Hilliard's death Canada has lost one of her most popular women doctors.

ROBERT RUTHERFORD, O.B.E., T.D., F.R.C.S.

Mr. Robert Rutherford, who was in general practice at Longtown, Cumberland, died suddenly at his home there on August 19. He was 63 years of age.

Robert Rutherford was born in Glasgow on January 23, 1895. As a child he moved with his parents to Carlisle, and was educated at Grosvenor College there. He left an apprenticeship with a chemist to serve with the Black Watch in France in the first world war. Soon after his return to civilian life he became a medical student at King's College Hospital, and qualified M.R.C.S., L.R.C.P. in 1927. Three years later he was admitted F.R.C.S. After qualification he held the appointments of house-surgeon at the Belgrave Hospital for Children and casualty officer, house-surgeon, and surgical registrar at King's College Hospital. From 1930 to 1934 he was clinical director at Hillingdon County Hospital, after which he was in general practice at Longtown. The author of many articles on surgical subjects published in this and other journals, he examined in surgery for the General Nursing Council from 1932 to 1939. As a Territorial officer he was recalled to the R.A.M.C. in 1939 on the outbreak of the second world war, and served throughout. He was officer in charge of the surgical division of the 19th General Hospital in England and Egypt in 1939-40; in command of the 60th British General Hospital in Palestine and India from 1940 to 1942; and officer in charge of the surgical division of the Davy Hulme Military Hospital in 1943 and the 110th British General Hospital in Normandy and Belgium in 1944-5. His name was brought to notice in recognition of distinguished services in connexion with operations in the field from March to June, 1940. Three years later he was awarded the Efficiency Decoration of the Territorial Army. In 1946 he was appointed O.B.E. for gallant and distinguished services in North-west Europe, and in the previous year he was mentioned in dispatches. After the war he returned to his practice at Longtown, becoming also medical officer to the Westmorland and Cumberland Yeomanry. He retired from the Territorial Army in 1952 with the rank of colonel. He married Miss Nora Borrett in 1931, and she survives him together with the two sons and three daughters of the marriage.

JAMES ALEXANDER, M.D.

Dr. James Alexander, who was in general practice at Galston, Ayrshire, for over half a century, died at his home in near-by Darvel on August 12. He was in his 90th year.

James Alexander was born at Waterside, in the parish of Fenwick, Ayrshire, on April 16, 1869, and was educated at Kilmarnock Academy and Glasgow University, where he graduated M.B., C.M. in 1890. Four years later he proceeded to the M.D. After graduation he was in practice at Aberdare, South Wales, and later went to Vienna for postgraduate study before returning to practise in Galston. He remained there for the next fifty-five years, and retired after the introduction of the National Health Service in 1948. A justice of the peace of the county of Ayr, he served as chairman of the Kilmarnock and district licensing court. He had great experience in both town and country practice, and leaves behind him a splendid record of public work and service.

J.S. writes: Dr. James Alexander's death ends, in this part of Ayrshire, the era of medicine which is slowly closing all over the country, when the general practitioner had to

use his skill in many branches of medicine without appeal for specialist help. Dr. Alexander was well fitted for this work. Robust and tall, he gave confidence with his firm manner and quick decisions, so that he built up a practice of grateful and loyal patients. For transport he used in his time, in turn, riding-horse, horse and carriage, and motor-car. Only recently, with failing health, did he lose his quick, energetic stride.

ANGUS CAMPBELL, M.C., M.B., Ch.B.

Dr. Angus Campbell, who died suddenly on August 11 at the age of 82 while holidaying with his younger brothers at Port Ellen, Isle of Islay, had been for many years in practice at Evenwood, near Bishop Auckland.

Angus Campbell was born on May 27, 1876, and graduated M.B., Ch.B. at Glasgow University in 1902. He began his professional career at Crook, Co. Durham, where he served for some years as assistant to the late Dr. McKay. On leaving there to take an assistantship for a short time in Pontypridd he received an illuminated address from his grateful patients. Throughout the first world war he served as a regimental medical officer in France, was mentioned in dispatches, and awarded the Military Cross. Soon after completing his military service, Campbell bought the farm of Giol in Oa, Isle of Islay, where his father had for many years been a sheep farmer. At this time, too, he settled at Evenwood in practice on his own account. He remained there until he retired at the age of 72, when he went to farm Giol, which had been managed for him by a younger brother. His wife Edith died there in 1955.

H.C.D. writes: A Highlander of retiring disposition, and of a quiet, gentle nature, Campbell had never sought a wide circle of friends, but to those who were privileged to be numbered among his intimates he was a loyal, forthright, and beloved friend. His forty years in Evenwood were devoted to his patients, his only recreation being an occasional hour with the gun and short visits to his beloved Islay. He had a profound knowledge of sheep and of sheep farming. Only a year ago he sold his farm and made his home with his eldest daughter. While it is a disappointment to his friends that he did not live longer to enjoy a well-earned rest, we feel that his sudden painless passing in the island that he loved so well would have been his wish. Dr. Campbell is survived by one son, Dr. Angus Campbell, of Oldham, and by three married daughters, and to them we extend our sincere sympathy.

W. BARRINGTON PROWSE, F.R.C., M.R.C.S. L.R.C.P.

Dr. W. Barrington Prowse, honorary consulting radiologist to the Royal Sussex County Hospital, Brighton, died at the hospital on August 16 a few weeks after his 88th birthday.

William Barrington Prowse was born on June 18, 1870, the son of Dr. William Prowse, and was educated at Epsom College. Receiving his clinical training at Bristol Royal Infirmary, he qualified M.R.C.S., L.R.C.P. in 1900. After a period of further study in radiotherapy at the London Hospital, he joined his father in general practice at Brighton. A few years later he decided to concentrate his energies on radiology, and in 1906 he set up in practice as one of the early specialists in the subject. A valued supporter of local and national medical organizations, he served as one of the honorary secretaries of the Section of Electrotherapeutics at the Annual Meeting of the British Medical Association held at Brighton in 1913, and he was chairman of the Brighton Division of the Association in 1935-6 and president of the Sussex Branch in 1937-8. He was also a past president of the Brighton and Sussex Medico-Chirurgical Society. A widower since 1951, he is survived by two sons, one of whom, Dr. C. Barrington Prowse, is a consulting physician.

G.W.B. writes: From the beginning of his career Dr. W. Barrington Prowse came to be known as a diagnostician of unusual ability. His opinion was a model of clarity and precision. His reports were always written by his own hand, a practice he never discontinued. From them a doctor would catch the reflection of a man who, though deeply versed in his craft, was also concerned for his patients beyond the narrow limits that craft imposed. During a long and flourishing working life his patients knew him as a man of great warmth and sympathy, and showed their appreciation for his many acts of kindness and consideration. He was responsible for the formation of a department of radiology at the Royal Sussex County Hospital and at Worthing Hospital. His professional life spanned the history of British radiology. Early in the century he was associated with the Roentgen Society and with the British Association for the Advancement of Radiology and Physiotherapy. In 1934 he was a founder member of the British Association of Radiologists, to which body he was elected a Fellow in the following year. The name of the parent body was changed in 1939 to the Faculty of Radiologists, and he was automatically made a Fellow. His private work reflected the development of radiology in general, from the Roentgen-ray equipment he installed at his consulting-rooms in 1906 to the later appearance of radiotherapy as a specialty and the increasing refinements of radiodiagnosis. Outside his work his interests were wide, principally in fishing and golf, and his keenness for swimming made him a familiar figure all the year round at the early morning bathing parade. His passing removes from medical practice in Sussex one of our most respected colleagues, and from the lives of those who knew him a most charming friend.

J. L. SHELLSHEAR, D.S.O., M.D., M.S.

Professor JOHN KIRK writes: I would like to express my grateful appreciation of the tributes to Professor J. L. Shellshear by two of his friends published in the *Journal* of August 16 (p. 453) and August 23 (p. 517). They have vividly recalled to me many happy memories of him in Hong Kong more than thirty years ago. In those days occasional visits to the Colony were a delightful experience for those of us whose work lay in the Chinese hinterland, especially because of the warm welcome which we knew was always waiting for us in the homes of our friends. In the medical school of the University of Hong Kong at that time were four great-hearted gentlemen who stood out pre-eminently and inevitably because of their valued contributions to medical education in the Far East. Joseph Shellshear occupied the chair of anatomy, H. G. Earle the chair of physiology, John Anderson the chair of medicine, and Kenelm Digby the chair of surgery. They were indeed a noteworthy quartet and the university was fortunate to have men of such character and ability to pass on to the eager Chinese students not only the best of Western medicine, but also those high ideals of life and service which were typical of each of those eminent teachers. "Joe" Shellshear was the last survivor of that wonderful group, to whose friendship I owed so much. Like his three valiant colleagues, he now rests from his labours and his works do follow him.

CORRIE HUDSON, C.B., C.I.E., D.S.O., F.R.C.S.Ed.

Lieutenant-Colonel H. R. B. GIBSON, I.M.S. (retired), writes: It has been suggested to me that I might make known incidents in the varied life of Major-General Corrie Hudson, of whom an obituary notice appeared recently in the *B.M.J.* (August 9, p. 392). In Bombay on February 12, 1914, Corrie Hudson had but recently returned from the 2nd Balkan War and that night he told me of his experiences there. He was at home on leave when he heard that Sir Frederick Treves was raising a British Red Cross ambulance to go to the Balkans. "C.H." got an interview with Sir Frederick, and on explaining the reason of his visit Sir Frederick smiled

and opened a drawer of his desk, showing that it was full of applications. Corrie Hudson, not a bit perturbed, asked, "How many of these applicants have commanded a field ambulance on active service?" Sir Frederick replied, "None. Have you?" "Yes," said Corrie. "That makes a difference," Sir Frederick said. "What position are you prepared to hold?" Corrie replied, "Either I command it or nothing." He got command. On the eve of his departure from the Balkans he was given a farewell dinner. He was shaking hands with the officers, when one said, "Not good-bye: au revoir. We shall meet in Berlin." At this the other officers laughed, and Corrie, seeing that there was something behind the remark, asked for an explanation. After an incredulous, "Don't you know?" the explanation was given, "Austria will declare war against Serbia, Germany will go with Austria. Against Germany and Austria will be Italy, France, Britain, Belgium, Holland, and Denmark. It is not good-bye but au revoir. We shall meet in Berlin." C. H. was greatly impressed, and on his return to London went to various departments of the War Office and attempted to impress them with the story. Eventually he got an interview with Sir Edward Grey, but there too he did not seem to have any success.

H. A. SANDIFORD, M.C., M.B., D.P.H.

The obituary of Brigadier H. A. Sandiford was printed in the *Journal* of August 23 (p. 513).

Dr. J. G. HUNTER, General Secretary of the Federal Council of the British Medical Association in Australia, writes: We here in Australia were grieved to learn of the death of Brigadier H. A. Sandiford, "Sandy," to all who knew him well, with his quizzical smile, warm welcome, and charm of manner, was a friend indeed to all overseas members visiting London, and the Commonwealth Medical Advisory Bureau is a monument to his enthusiasm to industry. I have the happiest of recollections of my association with Sandy during several visits to London, and on behalf of the Association in Australia I would like to pay tribute to the great work he did as director of the Bureau, and to extend deepest sympathy to his widow, son, and two daughters.

J. L. G. writes: I am one of those who have been deeply interested in the Commonwealth Medical Advisory Bureau since, and even before, its inception, and I would like to add my quota of admiration for the great work which Sandiford performed, and of sorrow at his death. His energy and organizing ability and, above all, his kindness of heart combined to create an instrument more efficient than even the most sanguine of us could have hoped. Scores of letters from overseas testify to the aid which he so cheerfully gave to visitors who might otherwise have remained friendless. The Bureau will be a lasting memorial to the man whose work as its first director must have helped in no small degree to strengthen the links between Britain and the other members of the Commonwealth.

Universities and Colleges

SOCIETY OF APOTHECARIES OF LONDON

The following candidates, having completed the final examination, have been granted the diploma of L.M.S.S.A.:

D. H. Perkins, J. R. Carling, M. C. Liu, I. H. Bailes, R. J. Priddy, J. R. Johnson, R. N. Brain, S. K. C. R. Villayarayan, M. A. Saber, E. M. Blenkinsop, P. W. F. Chan, N. Mustapha, J. A. Saunders, D. F. Fergie-Woods, M. T. Haslam, H. Hunt, E. McIlwaine, P. Nour-Eldin, J. F. Rivers, M. Budd, L. B. Cannell, A. J. Casson, M. A. Gibson, A. M. Hazell, R. G. Hornung, J. G. Williams.

P. R. Sathyanadhan was awarded the Diploma in Mastery of Midwifery and F. de S. Donnan, G. F. Smith, and W. O. Thompson the Diploma in Industrial Health.

Medico-Legal

FATAL AGRANULOCYTOSIS AFTER "NOVALGIN"

[FROM A HAEMATOLOGIST]

In 1945 a healthy man aged 45 was seriously injured in a road accident. After 17 weeks in hospital he was discharged with residual pain for which was prescribed "novalgin," an amidopyrine derivative, 5 gr. (320 mg.), and phenobarbitone, $\frac{1}{2}$ gr. (32 mg.), every night. All attempts to wean him from this combination failed, so that in the last 12 years he must have consumed some 1.5 kg. of novalgin and 150 g. of phenobarbitone.

In August, 1957, he had a chill and developed an inflamed mouth, diagnosed as thrush, from which he recovered completely. On January 30, 1958, he was found to have a second attack with bleeding from the gums and a haemorrhagic rash on thighs and arms. This time he did not respond to treatment and was admitted to hospital on February 6 with severe ulceration of the mouth, palate, and pharynx, generalized purpura, and bilateral basal pneumonia. A blood count showed virtually no leucocytes. His mouth swabs yielded profuse growths of monilia, streptococci, and haemophili. He died 55 hours later; necropsy confirmed the clinical findings. At the inquest the coroner recorded an open verdict, considering that the drug novalgin was responsible for the man's death (*East Anglian Daily Times*, March 13).

Comment

There seems no reason for doubting that the novalgin caused this man's death. It is a derivative of amidopyrine and no less dangerous. The makers have withdrawn their brand of amidopyrine from the British market, and do not advertise novalgin; but they still distribute it because there are a few people who seem to obtain relief from pain with no other analgesic drug. It was the manufacturers themselves who asked that novalgin should be placed on the Schedule of Poisons, and this was done in 1952.

This is the classical story of agranulocytosis as caused by amidopyrine and its derivatives. There is no reliable information about the frequency of this complication with these drugs, but estimates of up to 1% have been published.¹ It is now believed that agranulocytosis results from a sensitization process in which an antibody is formed to the leucocyte-drug complex; in the presence of the drug the leucocytes are agglutinated and filtered off in the lungs. If the drug is stopped, the bone marrow soon repairs the deficit, but if it is continued the bone marrow liberates ever younger cells, and ultimately all recognizable granulocyte precursors are destroyed.² In such cases recovery is unusual.

There are many drugs which may cause agranulocytosis, but only four groups are of much importance: first and most dangerous, because more potent than the others, amidopyrine and novalgin, still used in a few cases as analgesics, especially in combination with barbiturates under proprietary names, e.g., "amidophen," "amyltal compound," "cibalgin," "corosedine," "optalidon," "somnosal," "veramon," "veropyron" (but "allonal" and "taumasthman" no longer contain amidopyrine); secondly, phenylbutazone, sometimes the only drug which renders existence tolerable for the arthritic; thirdly, antithyroid drugs, especially the thiouracils; and, lastly, the anti-convulsants troxidine and methoin. Of course, occasional cases occur with almost any synthetic drug, including anti-histamines and sulphonamides.

The best way to prevent agranulocytosis is to avoid prescribing drugs which cause it; the analgesics containing a barbiturate with aspirin or with phenazone or a derivative can often replace an amidopyrine mixture, especially if used from the beginning, because many patients become reluctant to change from a proved friend. However, there will still remain a few people who may need the more

dangerous amidopyrine, many who will need phenylbutazone, and some who must take an antithyroid or anticonvulsant drug if they are not to become complete invalids. Such patients should be warned of the risks associated with their treatment, and told that they must report to their doctor at once if they develop a sore throat or fever; this should be the signal for an immediate leucocyte count. Most authorities doubt whether routine blood counts are worth the trouble, although Holliday³ has produced evidence which suggests that they may reduce the mortality. In addition, it is wise to make sure that any of these drugs should be dispensed in a container bearing its own name, lest the patient develops agranulocytosis far from home.

Once agranulocytosis has developed, it is essential to stop the drug at once, and any other drugs which might be involved, including all antituberculous drugs. The object of treatment is to prevent infection for the six or seven days until the bone marrow recovers, and this is usually done by giving penicillin. However, this might seem to invite invasion by penicillin-resistant staphylococci, so that nowadays a triple sulphonamide may be preferred. The patient should, if possible, be barrier-nursed in a cubicle fitted with ultra-violet sterilizing lamps. It is claimed that corticotrophin speeds up bone-marrow recovery.⁴ Blood transfusion may help in severe anaemia. The prognosis, of course, depends entirely on the speed with which the condition is recognized and administration of the offending drug discontinued.

Vital Statistics

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the years 1949-57 are shown thus -----, the figures for 1958 thus ————. Except for the curves showing notifications in 1958, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Week Ending August 23

The largest fluctuations in the number of notifications of infectious diseases in England and Wales during the week ending August 23 were a decrease of 1,306 for measles, from 5,102 to 3,796, 61 for food-poisoning, from 287 to 226; 47 for scarlet fever, from 373 to 326; 32 for acute pneumonia, from 183 to 151; and an increase of 57 for whooping-cough, from 713 to 770; and 46 for dysentery, from 338 to 384. The largest falls in the incidence of measles were 150 in Lancashire from 615 to 465, 150 in Middlesex from 341 to 191, 78 in Cornwall from 130 to 52, and 62 in Hampshire from 146 to 84. Only small fluctuations were recorded in the local trends of scarlet fever and whooping-cough. Only two cases of diphtheria were notified—the same number as in the preceding week.

The notifications of acute poliomyelitis numbered 77, and there were 15 fewer paralytic and 6 more non-paralytic cases than in the preceding week. The largest returns were Yorkshire West Riding 20 (Leeds C.B. 5, Huddersfield C.B. 2, Hemsworth R.D. 2), Lancashire 8 (Burnley C.B. 2, Manchester C.B. 2), and Devonshire 5 (Plymouth C.B. 5). After falling for 6 consecutive weeks the number of notifications of dysentery rose slightly. The chief centres of infection were Yorkshire West Riding 78 (Thorne R.D. 17, Leeds C.B. 15), Lancashire 60 (Liverpool C.B. 24), London 55 (Islington 11, St. Pancras 10), and Gloucestershire 30 (Bristol C.B. 30).

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Age and Severity of Poliomyelitis

Q.—Is poliomyelitis infection likely to be "more harmless" in infants and young children than in older children and adults?

A.—The outcome of an infection by the virus depends upon the pre-existence of antibodies in the serum which will prevent viraemia and involvement of the C.N.S. and also on the susceptibility of the neurones to attack. The levels of antibodies in the serum increase rapidly in early childhood, except when exposure to the virus has been prevented by good sanitation. Nevertheless, even in civilized communities most children of school age possess antibodies, so that the likelihood of poliomyelitis infection involving the C.N.S. diminishes steadily with age. The mortality rate from paralytic disease increases, however, with age, probably because adult neurones are more readily damaged than are those of infants or children. Serious residual effects or death are therefore more often seen when the paralytic disease occurs in an older child or an adult. In this sense therefore polio is more harmless in the young infant than in the older child or adult.

Prednisolone for Infantile Eczema

Q.—Is there any risk in using oral prednisolone in the treatment of acute exacerbations of infantile flexural eczema in a girl aged 11?

A.—All steroid hormonal therapy carries risks, and their use is undesirable especially in children approaching puberty. This is particularly so in a chronic affection like flexural eczema, which can generally be brought under control by other means. The use of such hormonal therapy may be justified occasionally to control severe exacerbations. In the severe type of Besnier's prurigo with xeroderma, chronic eczema, asthma, and sometimes juvenile cataract formation, the incurable condition may make life so distressing and relief from moderate dosage of steroid hormones may be so marked that their use on a long-term basis may even be justified, but these are exceptional circumstances.

Encephalitis and Concurrent Vaccinations

Q.—How real is the danger of encephalitis when primary smallpox and yellow fever vaccinations are carried out at the same time? Is there still a danger in concurrent vaccination in an adult who had primary smallpox vaccination in childhood but has not been revaccinated since?

A.—In infants aged under 9 months a small number of cases of a mild encephalitic syndrome—fever, drowsiness, and muscular twitchings—have been reported about ten days after yellow fever vaccination. As primary smallpox vaccination also carries a danger of encephalitis, there is presumably a greater risk of neurological complications when both viruses are inoculated concurrently. It is deemed safer, therefore, in infants to leave an interval of at least 21 days between the two vaccinations whichever is done first; but yellow fever vaccination should in fact be postponed, wherever practicable, till the age of 9 or even 12 months.

In the case of older children and adults, the danger of encephalitis after yellow fever vaccine is negligible, but the danger of encephalitis after primary smallpox vaccination remains. When both vaccinations have to be done, the Ministry of Health recommends that yellow fever vaccination should precede smallpox vaccination by an interval of not less than four days. There are no known published

statistics giving the degree of risk if this wise precaution is not followed and both vaccinations are done at the same session.

The risk of encephalitis from concurrent vaccination is less still in the case of an adult who has had primary smallpox vaccination in childhood. Nevertheless, it is better to play for safety and to give yellow fever vaccine first and the smallpox vaccine four days later.

Carcinogens in Fertilizers

Q.—Is there a danger of fertilizers and insecticides making crops and fruit carcinogenic to the consumer?

A.—No material generally recognized to be carcinogenic is used in agriculture under conditions in which a residue might persist in the crop as it is consumed. When the question was raised in the specific case of a weedkiller—maleic hydrazide—an elaborate series of tests showed the supposition that it might be a carcinogen to be groundless.¹ When there are no special reasons for apprehension about a substance, such detailed investigations are not carried out, but routine toxicity tests are done, including the feeding of animals with the substance for a period of one to two years. This should give a reasonable chance for detecting any carcinogenic properties.

Salt-losing Nephritis

Q.—Is sodium chloride indicated in salt-losing nephritis in the presence of considerable oedema, and should diuretics be used?

A.—If the patient has developed oedema there must be retention of salt and water by the kidneys, and if, therefore, salt-losing nephritis was once present it is no longer. The development of oedema in a patient with salt-losing nephritis is so unusual as to make one wonder whether the initial diagnosis was correct. None the less, it is theoretically possible for sodium retention to occur, even though the tubular transport of sodium is severely impaired, if the glomerular filtration rate becomes markedly depressed. Diuretics may be used to eliminate the oedema but should be used cautiously if there is any elevation of the blood urea.

Correction.—In Dr. A. C. E. BREACH's note describing an adjustable bed (*Journal*, August 23, p. 506), one of the advantages claimed for the bed was that "the orthopaedic patient can adjust his position, day or night, to give maximum comfort and can vary it at will." This should have referred to the *orthopaedic*, not the *orthopaedic*, patient.

Collected Articles from the "British Medical Journal"

The following books are available through booksellers or from the Publishing Manager, B.M.A. House. Prices, which include postage, are now the same for both inland and overseas.

LUNG CANCER DEATH RATES IN ENGLAND AND WALES COMPARED WITH THOSE IN THE U.S.A.

BY

E. CUYLER HAMMOND, Sc.D.

Director, Statistical Research Section, Medical Affairs Department, American Cancer Society, Inc.

The large differences between reported lung cancer death rates in England and Wales and in the United States have not yet been explained satisfactorily. A study of these differences may well lead to a better understanding of the aetiology of this disease. While the data available at the present time are inadequate for the purpose, they are worth discussing as a basis for further investigations.

The lung cancer death rate reported by the Registrar General for England and Wales in 1955 was 69.3 per 100,000 population for males and 10.6 per 100,000 for females. Standardizing the lung cancer death rates reported by the National Office of Vital Statistics for the United States in 1955 to the age distribution of the population of England and Wales in 1955, the rates were only 33.0 per 100,000 population for males and 6.7 per 100,000 population for females. In other words, the lung cancer death rate in England and Wales for males was 2.1 times as high as in the United States and for females 1.6 times as high. These ratios did not vary greatly in different age groups. For example, among males the ratio of the rate in England and Wales to the rate in the United States was 1.9 in age group 25-34; 2.0 in age group 35-44, 2.0 in age group 45-54; 2.2 in age group 55-64; 2.1 in age group 65-74; and 1.8 in age group 75-84.

Fig. 1 shows reported lung cancer death rates for males and females in age group 45-54 for England and Wales and for the United States from 1931-5 to 1956. The rates for the United States are for the white population only. Fig. 2 is similar but for age group 65-74. For males in both countries and both age groups the rates increased rapidly during this period of time. Within each age group the trend lines (plotted on semi-log paper) are roughly parallel for the two countries, but at a much higher level for England and Wales than for the United States. After 1948 the rate of increase was less in age group 45-54 than in age group 65-74.

The picture is somewhat different for females. From 1931-5 to 1948 the female rates in each of the two groups were only slightly higher in England and Wales than in the United States and generally increased in both countries during this period of time. The female rates continued to increase after 1948 in England and Wales but not in the United States.

It should be noted that a small number of deaths from cancer of the respiratory system other than the lungs—for example, pleura, trachea, and mediastinum—are included in some of the figures quoted above. These

inclusions are slightly different in figures from the two countries. However, the effect of this is trivial, since all but a very small percentage of the deaths are presumed to have been due to bronchogenic carcinoma.

Both the form of the death certificate and the rules for classifying deaths by cause were changed in the United States as from January 1, 1949. Changes in the rules for classification were also made in England and Wales in 1949, while the form of the death certificate had been changed at an earlier date.

The changes in reporting procedures in the United States may be responsible for the change in the trend lines for females which occurred after January 1, 1949. However, if this explanation is correct, it is hard to see why a change of similar magnitude did not occur in the trend lines for males.

Cigarette Smoking

There is evidence that, in both countries, lung cancer is highly associated with cigarette smoking (Doll and Hill, 1956; Hammond and Horn, 1958a, 1958b). Let us consider the hypothesis that differences in degree of exposure to cigarette smoke (or certain components of the smoke) account for the reported differences in lung cancer death rates between the two countries.

At least five different factors may be of importance in determining the degree to which the lungs of a cigarette smoker are exposed to important ingredients of the smoke. These are: (1) the average number of cigarettes smoked per day, (2) the number of years of smoking, (3) the degree to which the smoke is inhaled, (4) the proportion of each cigarette which is actually smoked, and (5) the amounts of various chemical ingredients in the main stream smoke of the cigarette. These are discussed in turn.

Average Daily Consumption

Cigarette smoking apparently became popular at an earlier date in the United Kingdom than in the United States. In 1935 the consumption per adult per annum of packeted cigarettes is reported to have been 1,589 in the United Kingdom and 1,410 in the United States (Todd, 1957). Cigarette consumption increased in both countries, but to a greater extent in the United States than in the United Kingdom. In 1956 the reported consumption per adult per annum of packeted cigarettes was 2,509 in the United Kingdom and 3,195 in the United States. The increase in total cigarette consumption was probably slightly less than these figures appear to indicate, since there was a decline in the use of hand-rolled cigarettes. It is also possible that more

FIG. 1.—Lung cancer death rates, by sex, at age 45-54 for England and Wales and United States (white population) in 1931-5 to 1956. Source of data: Registrar-General of England and Wales and United States National Office of Vital Statistics.

FIG. 2.—Lung cancer death rates, by sex, at age 65-74 for England and Wales and United States (white population) in 1931-5 to 1956. Source of data: Registrar-General of England and Wales and United States National Office of Vital Statistics.

hand-rolled cigarettes are now being smoked in the United Kingdom than in the United States. In the United Kingdom in 1956, 7.0% of all male cigarette smokers and 0.2% of all female cigarette smokers said that they smoked only the hand-rolled variety. However, 12.7% of male cigarette smokers in age group 60 and older still smoked only hand-rolled cigarettes. Information on this is not available for the United States.

For a proper comparison of cigarette consumption in the two countries one would need to know for each sex and for each five-year or ten-year age group the proportion of people who smoke cigarettes at each of several levels of number per day. This information is available for the United States for 1955 (Haenszel, Shimkin, and Miller, 1956) but is not available in such detail for the United Kingdom. However, some very useful data on the subject have been reported by the Tobacco Manufacturers' Standing Committee (Todd, 1957) for the United Kingdom in 1956. These are summarized in Tables I and II. Unfortunately, differences in age groupings and possible differences in definitions make comparisons between the two countries a bit difficult. About 4% of the people interviewed in the United States said that they smoked cigarettes "once in a while, not every day." These have been included as cigarette smokers in Tables I and II because the same procedure seems to have been used in the study in the United Kingdom.

TABLE I.—Percentage of People Smoking Cigarettes by Age and Sex in the United Kingdom and in the United States of America

United Kingdom, 1956				United States, 1955			
Age	% Smoking Cigarettes			Age	% Smoking Cigarettes		
Males				Males			
16-24	60.7	18-24	59.3				
25-34	70.9	25-34	69.2				
35-59	71.0	35-44	68.0				
60 and over	52.6	45-54	63.5				
		55-64	51.1				
		65 and over	29.5				
Total	66.0	Total	59.2				
Females				Females			
16-24	39.2	18-24	37.7				
25-34	51.8	25-34	43.0				
35-59	44.7	35-44	38.9				
60 and over	28.8	45-54	29.0

TABLE II.—Percentage Distribution of Cigarette Smokers by Number Smoked Per Day for Males and Females in the United Kingdom in 1956 and the United States of America in 1955

Cigarettes Per Day	Males		Females	
	U.K.	U.S.A.	U.K.	U.S.A.
< 10	25	23	55	45
10-20	57	53	40	47
> 20	18	24	5	8
Total	100	100	100	100

In age group 16-24 in the United Kingdom and age group 18-24 in the United States it appears that the proportion of people who smoke cigarettes is about the same in the two countries. The same is true of males in age group 25-34. In all other groups, particularly in the old-age group, it appears that a larger percentage of people smoke cigarettes in the United Kingdom than in the United States. The difference is most marked among women in age group 60 and older.

These figures suggest that the difference in reported lung cancer death rates between England and Wales and the United States may be partly due to the fact that there are

proportionally more cigarette smokers in the former than in the latter country (in age groups where lung cancer most frequently occurs). However, if this be true, it would seem that the ratio of the lung cancer death rate in the United Kingdom to the lung cancer death rate in the United States should increase with age and be highest in women in the old-age group. This does not appear to be the case.

For all age groups combined it appears that a somewhat larger percentage of cigarette smokers are in the over-20-cigarettes-a-day class in the United States than in the United Kingdom (see Table II). This should tend to nullify some of the effect (on lung cancer death rates) of the larger proportionate number of cigarette smokers in the United Kingdom than in the United States. Unfortunately, these figures are not available by age groups (which might perhaps alter the picture).

Number of Years of Smoking

There is reason to suppose that, other things being equal, the longer a person has smoked cigarettes the greater is the likelihood that he will develop lung cancer. Since smoking became popular at an earlier date in the United Kingdom than in the United States, it may be that there is a larger proportion of long-time cigarette smokers in the former country than in the latter. However, the great majority of men in the United States in age group 50-69 who are currently smoking cigarettes took up the habit before reaching the age of 25 (over half took it up before the age of 20) (Hammond and Horn, 1958a). This being the case, it seems unlikely that a difference, if any, in the number of years that cigarette smokers have been addicted to the habit could account for the large difference in lung cancer death rates between England and Wales and the United States.

Inhaling

A study by Schwartz and Denoix (1957) seems to indicate that, holding age, sex, type of smoking, and amount of smoking constant, smokers who inhale run a greater risk of lung cancer than do smokers who do not inhale. Data reported by the Tobacco Manufacturers' Standing Committee (Todd, 1957) indicate that the proportion of cigarette smokers who inhale: (a) increases with amount of smoking, (b) decreases with age, and (c) is greater among men than among women. We have recently made a study of inhalation in relation to age, type of smoking, and amount of smoking among men in the United States (Hammond, 1958). The findings of our study are in agreement with those of the British study.

In the British study the men were asked the simple question, "Do you inhale?" In our study the subjects were asked how much they inhale, given the choice between "do not inhale," "inhale slightly," "inhale moderately," and "inhale deeply." We are under the impression that the answers "inhale moderately" and "inhale deeply" taken together are roughly comparable to the answer "yes" in response to the question, "Do you inhale?" The following comparisons are valid only if this assumption is correct. Disregarding age, amount of cigarette smoking, and whether pipes and cigars were smoked as well as cigarettes, the proportion of male cigarette smokers who inhale is about

84% in the United Kingdom and about 82% in the United States. Among men under 60 years of age who smoke about a pack of cigarettes a day (or 15 to 24 cigarettes), about 91% inhale in the United Kingdom and 88% inhale in the United States. The comparable figures for age group 60 and older are 67% for the United Kingdom and 65% for the United States. These percentages for the two countries are remarkably close.

Proportion of Cigarette Smoked

Much of the tar and nicotine volatilized just behind the burning tip of a freshly lit cigarette is condensed as it is drawn through the cigarette towards the mouth of the smoker. This condensed material is largely revolatilized as smoking continues. As a result, the smoke from the last part of a cigarette which can be smoked is far richer in these ingredients than is the smoke from the portion first consumed. Some observers are under the impression that American smokers often discard a cigarette after taking only a few puffs, while this seldom happens in the United Kingdom. If true, this might make an appreciable difference in the degree to which smokers in the two countries are exposed to tobacco smoke.

Since casual observations can be very misleading, I have undertaken to collect some data on this subject in the United States, hoping that data for comparison will soon be available in the United Kingdom. There is no information on what factors influence the extent to which each cigarette is smoked, but it seems likely that the location and current activities of the smoker as well as individual idiosyncrasies play a part. With this in mind, I had 4,283 discarded cigarette butts collected from a variety of different locations, including business offices, private homes, restaurants, sidewalks of city streets, railroad and bus stations, and a public park. The collection was carried out in four large cities (Los Angeles, Chicago, Pittsburgh, and New York) and several smaller cities and towns (Harrisburg and Bradford, Pennsylvania; Oak Park, Wheaton, and Brookfield, Illinois; and Albany, New York). The butts were divided into those with filter-tips and those without filter-tips. Each butt was straightened out and the length of the remaining paper was measured. When the paper was burned farther down on one side than on another, the average length of the remaining paper was recorded. The results are shown on Table III.

The average length of all the butts was 30.9 mm., being 31.0 mm. for those with filter-tips and 30.7 mm. for those without filter-tips. Only 0.2% of the butts with filter-tips and 1.8% of those without filter-tips measured less than 15 mm., while 8.2% and 9.4% respectively measured less than 20 mm. Most filter-tip cigarettes are 85 or 80 mm. in total length, of which 17 or 18 mm. is taken up by the filter; but some are shorter in total length and some have shorter filters (the average length being about 82 mm.). About two-thirds of the cigarettes without filters sold in the United States in 1957 measured 70 mm. and most of the remainder measured 85 mm., the average length being about 75 mm. Since both filter-tip and non-filter-tip butts average about 31 mm. in length, it appears that on the average about

TABLE III.—Lengths of Cigarette Butts Collected from Various Locations in the United States of America in 1958

Location or Type of Cigarette	No. of Butts	Mean Length in mm.	Length of Butts in mm.										
			< 15	15-19	20-24	25-29	30-34	35-39	40-44	45-49	50-54	55 +

38% of each filter-tip cigarette and about 41% of each non-filter tip cigarette is discarded.

At my request, Dr. Remmert Korteweg has collected and measured cigarette butts discarded by several different groups of people in the Netherlands and has kindly given me permission to publish his findings. Altogether, 545 butts were measured. The mean length was only 19.7 mm.; 19.6% were less than 15 mm. in length and 55.6% were less than 20 mm. in length. Dr. Korteweg warns that these are preliminary figures. Nevertheless, the very large difference between his findings in the Netherlands and my finding in the United States is suggestive. If an equally large difference of this kind exists between the United Kingdom and the United States, it may well account for the difference in reported lung cancer death rates.

There are some obvious difficulties in the method used in this study of cigarette butts. For one thing, the cigarette butts collected may not have been reasonably representative of all the cigarette butts discarded in the United States in the early part of 1958. More important, it is questionable whether the length of a discarded cigarette butt is a reliable index of the amount of smoke which was drawn into the mouth of the smoker. For example, lighted cigarettes are sometimes left to burn out in an ash-tray or on the ground. Furthermore, much of a cigarette may burn up while being held in the hand or left in an ash-tray between puffs. Thus a short butt does not necessarily indicate that most of the potential smoke from the cigarette was drawn into the mouth of a smoker. On the other hand, a long butt is sure proof that the smoker failed to avail himself of a large proportion of the potential smoke. In spite of these difficulties, I hope that the method is sufficiently reliable to reveal a large difference in this respect between Great Britain and the United States if a large difference in fact exists.

Chemical Composition of the Smoke Stream

Cigarettes were very much a standard product in the United States up until a few years ago. Now there are a great variety of types on the market, including "regular size" and "king size"; those without filter-tips and those with filter-tips of various degrees of effectiveness; some with the nicotine partly removed from the tobacco; and some with types of tobacco producing relatively low nicotine and tar in the main stream smoke. In addition, some brands with filter-tips began to contain more heavy burley-type tobacco and less light flue-cured tobacco in their blends. This probably nullified the benefit, if any, to be derived from the filter-tip.

In the middle of 1957 the amount of nicotine in the main stream smoke of the more popular brands of cigarettes in the United States varied from about 1.8 to 3.1 mg. and the amount of tar varied from about 25.6 to 42.8 mg. (Miller and Monahan, 1957a). If the number of cigarettes of each brand sold (Wooten, 1957) and the composition of the smoke are taken into account, the main stream smoke of the average cigarette had about 2.6 mg. of nicotine and 28.8 mg. of tar. Later that year a filter-tip cigarette with only 1.1 mg. of nicotine and 19.7 mg. of tar in the main stream smoke was put on the market (Miller and Monahan, 1957b). It immediately became popular, probably owing in part to an article on the subject which appeared in an influential magazine. To-day there are several additional low nicotine and low tar brands on the market. There have been no reports on the content of carbon monoxide and other gases in the main stream smoke of these cigarettes as compared with others. It appears that these new cigarettes are selling well. It remains to be seen whether they will eventually replace the old type and, if so, whether smokers will be benefited in terms of health.

Other Environmental Factors

Now let us consider the hypothesis that some environmental factor other than smoking entirely accounts for the difference in lung cancer death rates between the two countries.

It is well established that lung cancer can be caused by many years of heavy exposure to dusts of certain types—for example, radioactive minerals, chromates, and nickel (Hammond and Machle, 1956). Hueper (1955) has expressed the opinion that workers in various industries are exposed to a great many different substances (in the form of dust, gas, or vapour) that are of aetiological significance in lung cancer. This is difficult to prove one way or the other, because it is usually hard to find sufficiently large groups of workers who have had long exposure to known concentrations of specific dusts. Many of the dusts under suspicion in relation to lung cancer—for example, asbestos and beryllium—produce other serious effects upon the lungs. For this reason, intensive efforts have been made in the United States and elsewhere to protect workers from undue exposure. Presumably this would reduce or eliminate any potential lung cancer hazard.

General air pollution has long been under suspicion. The substances most often mentioned in this respect are: (a) fumes from motor vehicles and oil furnaces, (b) combustion products of coal, and (c) dust from asphalt roads. All of these contain small quantities of known carcinogenic substances. In addition, certain industrial plants discharge fumes which produce air pollution in the surrounding area. Some of these fumes may contain carcinogenic substances. The fact that these air pollutants contain carcinogenic substances does not necessarily prove that they cause lung cancer.

What concerns us here is whether a difference between England and Wales and the United States in respect to either occupational exposures or general air pollution could account for the differences in lung cancer death rates. Stocks and Campbell (1955) have studied lung cancer rates among men aged 45 to 74 in relation to type and amount of smoking in Liverpool compared with several small English cities and a rural area in Wales. There is considerable air pollution in Liverpool, and the Liverpool area has a high lung cancer death rate. There is almost no air pollution in the rural areas studied. In each of these areas the lung cancer death rate was found to be of the order of magnitude of 300 per 100,000 population per year higher for heavy cigarette smokers than for non-smokers. Among non-smokers and smokers alike, the lung cancer death rate was roughly 100 per 100,000 per year higher in Liverpool than in the rural area of Wales. The lung cancer death rate in the small cities was about the same as in the rural areas. Hammond and Horn (1958b) have studied lung cancer death rates in relation to smoking habits among men aged 50-69 in large cities, small cities, and rural areas of the United States. The rate was about 250 per 100,000 per year higher among heavy cigarette smokers than among men who never smoked. Both for smokers and non-smokers the lung cancer death rate was roughly 20 per 100,000 per year higher in large cities than in rural areas.

Since the data quoted above are almost the only information available on the subject for the moment, let us assume: (a) that air pollution, occupational exposure, or some other factor associated with urbanization produces an increase in the lung cancer death rate, and (b) that the force of this effect among males in age group 50-69 is 80 per 100,000 population per year greater in English and Welsh cities than in cities in the United States. Further, let us assume that this differential applies to three-fourths of the male population of both countries (people living in rural areas and cities such as Chester and Wrexham not being affected). Under these assumptions, the lung cancer death rates of males in age group 50-69 should be about 60 per 100,000 higher in England and Wales than in the United States.

In 1956 the reported lung cancer death rate among males in age group 50-69 was 233 per 100,000 in England and Wales and 115 per 100,000 in the United States, a difference of 118 per 100,000. This reported difference is about twice as large as might be expected on the basis of the hypothesis outlined above. Thus, even assuming that Liverpool is typical of all urban areas in England and Wales, it appears

that the difference in male lung cancer death rates between England and Wales and the United States cannot be attributed entirely to differences in air pollution or occupational exposures. Actually, Liverpool is far from typical. According to a report of the Registrar General (1957), the male lung cancer death rate in Merseyside (which includes Liverpool) is higher than in any other region of England and Wales and is 42% higher than for England and Wales as a whole. Furthermore, it is no criticism of the excellent work of Stocks and Campbell to say that it is difficult to obtain an accurate estimate of the lung cancer death rate of non-smokers and that their findings have not yet been verified by other investigators or in other cities with heavy air pollution.

Climate is another factor which cannot be ignored. In some heavily populated areas such as London and Los Angeles peculiar atmospheric conditions produce episodes of "smog" from time to time. From what little evidence is available, it appears that a far larger proportion of the population live in areas where this is a problem in England and Wales than in the United States. In addition, the climate of the British Isles is apparently such as to produce a higher incidence of bronchitis than in the United States. While it seems unlikely that bronchitis alone can result in lung cancer, it is not unreasonable to postulate that bronchitis increases the susceptibility of an individual to the carcinogenic effect of some other factor such as cigarette smoke or air pollutants.

Accuracy of Diagnosis

Finally, let us consider the hypothesis that differences in diagnosis and recording of deaths by cause entirely account for the difference in lung cancer death rates between the two countries.

The problem of accuracy of diagnosis plagues us whenever we attempt to compare death rates from cancer of specific sites in different periods of time, different countries, or different sections of the same country. For example, there is reason to suspect that lung cancer, when present, is somewhat more likely to be diagnosed in urban areas than in rural areas of the United States (doctors and medical facilities being concentrated in cities). This being the case, we are not at all sure that the small difference between urban and rural areas in lung cancer death rates among men with the same smoking habits is real or whether it is merely the result of differences in diagnosis. Likewise, it is reasonable to suppose that, owing to improvements in medical science, lung cancer is more likely to be correctly diagnosed to-day than it was thirty or forty years ago. It seems likely that some of the apparent rise in lung cancer death rates was due to the improvement in diagnosis (Dorn, 1954).

If the difference in lung cancer death rates between England and Wales and the United States is merely the result

FIG. 3.—Male cancer death rates (standardized for age on 1940 U.S.A. population) for England and Wales and United States (U.S.A. figures for white males) in 1936-56.

of a difference in the level of diagnosis, then (a) British physicians are making this diagnosis in about twice as many men as actually have the disease, or (b) American physicians are missing about half the cases that actually occur in men, or (c) British physicians tend to err in one direction and American physicians tend to err in the other direction.

Some other respiratory disease may sometimes be recorded as the cause of death when the patient actually died of lung cancer. However, among white males aged 50-64 in 1955 in the United States, 9,789 deaths were attributed to lung cancer and only 9,112 deaths were attributed to all other respiratory disease combined (including pulmonary tuberculosis, influenza, pneumonia, etc.). Even if half of the deaths attributed to other respiratory diseases were actually due to lung cancer, it would not account for the entire difference in lung cancer deaths between England and Wales and the United States.

Fig. 3 shows the death rates from cancer of all sites and cancer of all sites except the lung for males in the two countries for the period 1936 to 1956. For comparability, the rates have been standardized for age on the age distribution of the population of the United States in 1940. The figures for the United States are for white males only.

The reported total cancer death rate (age-standardized) increased in the United States during this entire period of 20 years and increased in England and Wales from 1944 onward. In all of these years the rate was far higher in England and Wales than in the United States. The interesting fact shown on this chart is that when lung cancer is excluded the rate went steadily down in England and Wales from 1936 to 1956 while it rose slightly in the United States during the same period of time. This may be a true picture of what actually occurred. On the other hand, it may be a clue to a part of our puzzle.

We have reason to believe that cure rates for cancer of some sites improved somewhat in the United States during this period of time (Hammond, 1957). We have no reason to believe that there was a real increase in incidence rates of cancer of sites other than lung. When cancer kills, it is usually widespread in the body at the time of death, and in many cases it is by no means easy to ascertain the site of origin of the disease. These facts suggest the following hypothesis. When cancer is present at the time of death both in the lungs and in other parts of the body and the primary site cannot be determined with accuracy, there is a tendency in England and Wales to record lung as the primary site and a tendency in the United States to record some other organ as the primary site.

This hypothesis, if true, would account for a part of the difference in lung cancer death rates between the two countries; but it would not explain why the total cancer death rate among males is far higher in England and Wales than in the United States. One would further have to assume that cancer (regardless of primary site) is either over-reported as a cause of death in England and Wales or under-reported in the United States, or both.

Conclusions

There must be some explanation for the fact that reported lung cancer death rates for men are about twice as high in England and Wales as in the United States and the rates for females are about one and a half times as high in England and Wales as in the United States.

Data at present available do not support the hypothesis that a substantial part of this difference can be attributed to differences in amount of cigarette smoking among males and females in various age groups in the two countries. However, more detailed information on smoking habits and on the chemical composition of smoke from cigarettes in the two countries is needed before this can be definitely established.

While it is possible that some of the difference in lung cancer death rates may be due to factors associated with urbanization—for example, air pollution or occupational

mild hyaline change in some of the veins and a short segment of medial thickening in the anterior spinal artery, no other vascular abnormality was found. The spinal cord from T10 downwards showed a bilaterally symmetrical degeneration of uniform severity (see Fig.). The anterior horns were atrophied, with loss of motor neurones, and showed a round-celled infiltration. The lateral and anterior columns showed incomplete demyelination, the pyramidal tracts being spared. The posterior columns were unaffected. The sections from the segments below T10 showed that these changes were clearly confined to the anterior part of the cord in the distribution of the anterior spinal artery.

Transverse section of spinal cord at the level of S2, showing the symmetrical degeneration of the cord in the distribution of the anterior spinal artery. (Stained with methasol. $\times 6$.)

Discussion

In this patient the choice of anaesthetic was based on the following considerations. The state of his cardiovascular system, together with the bronchopneumonia and severe emphysematous changes in his lungs, made it appear wiser to use some form of local anaesthetic. Also, there was the added hazard of inhalation of vomit which might well have occurred under general anaesthesia. The choice of local anaesthetic in our minds lay between subcutaneous infiltration and local nerve block, spinal or epidural. It was thought that the inflammatory changes present over the hernial sac and inguinal ligament were sufficient to make it inadvisable to use either the subcutaneous method or the local nerve block. Spinal anaesthesia is less often used in this country, and was rejected because of its risk of nervous sequelae. Epidural anaesthesia was used because of the advantage of obtaining a pure sensory block, thus obviating any respiratory embarrassment due to motor paralysis. In addition, the unexplained bronchodilator effect of the epidural anaesthetic would be beneficial to this patient's emphysematous condition (Bromage, 1954). These advantages were considered to outweigh the risk of hypotension that might result. It was possible to prevent a further fall in blood pressure by using a moderate dose of ephedrine, without having to resort to the stronger vasopressor drugs, such as noradrenaline.

From the clinical picture and the pathological and histological findings our patient was quite clearly suffering from the syndrome of anterior spinal artery occlusion. Other causes for the paraplegia that might be related to the anaesthetic technique, such as disk protrusion, extradural haemorrhage, and haematomyelia, were considered. The disk protrusion could have been caused by flexion of the spine during the induction of anaesthesia. Extradural haemorrhage either spontaneously occurring through twisting or straining (Schultz *et al.*, 1953) or traumatic in origin by damage to the spinal veins, may have resulted. Haematomyelia may have been caused by damaging the cord. All these possible events were excluded on the

pathological findings. Further consideration must be given to the possibility that an accidental spinal anaesthesia was induced, causing the paraplegia. On clinical grounds this was excluded because the patient was able to move his legs some while after the epidural anaesthetic was given. But Sykes (1958) points out that this sign is not infallible, and a spinal anaesthesia may have resulted through seepage via a small dural puncture. A total spinal anaesthesia can be excluded on the grounds that there was no respiratory paralysis, no profound fall in blood pressure, or, as would be expected with a quantity of anaesthetic of this magnitude, no loss of consciousness and no pupil signs developed.

Two further causes of the neurological damage—chemical contamination of the spinal cord and infection—have to be excluded. The former can be ruled out because no chemical agent was used to sterilize the anaesthetic solution or the instruments. The possibility of the introduction of infection does not seem likely, because of the aseptic technique adopted. This consisted of autoclaving drums (30 minutes at 20 lb.), the use of sterile gowns and gloves, and the preparation of the skin over the lumbar region with Bonney's blue and 70% surgical spirit. Clinically, the onset of the paraplegia was rapid enough to make it unlikely that there was an infective cause. Furthermore, the absence of adhesive arachnoiditis at post-mortem examination ruled out both these possibilities.

It should also be mentioned that cases of paraplegia have been reported as occurring after general anaesthesia. These were due to either a thrombosis following hypotension (Ciliberti, 1948; Ditzler and McIver, 1956) or to air embolism during the induction of an artificial pneumothorax (Wikler *et al.*, 1937) or injury to the pulmonary vein during thoracotomy (Thomas and Dwyer, 1950).

Finally, the epidural anaesthetic as the prime cause of the paraplegia must be discussed. Because of the known hypotensive action of an epidural anaesthetic, precautions were taken at the onset to prevent a severe fall in blood pressure. However, a systolic pressure between 80 and 100 mm. Hg might well have been too low to maintain an adequate blood supply to the cord with his already failing circulation. This might possibly have led to stasis and subsequent thrombosis in the vessels. We are aware of a similar case where a temporary paraplegia resulted from the use of an epidural anaesthetic to provide controlled hypotension for a total parotidectomy (Massey Dawkins, 1958, personal communication).

The stasis might have been produced by compression of the spinal vessels by the volume of local anaesthetic solution introduced into the epidural space. This almost certainly can be excluded, for there is easy dispersion of the solution through this space and the paravertebral foramina. Furthermore, it would be more likely for the posterior spinal vessels to be affected rather than the anterior.

Many authorities have suggested that the local anaesthetic itself may cause permanent neurological damage (Payne and Bergentz, 1956). Frumin *et al.* (1953) have produced strong experimental evidence that the anaesthetic solution will diffuse from the epidural space into the spinal canal. Most of the local anaesthetic drugs have been incriminated in producing cord damage, but, so far as we can ascertain, no report following the use of lignocaine hydrochloride has been made. However, it would seem likely that this too might have a similar action on nervous tissue. From the clinical signs and the pathological findings of damage solely in the distribution of the anterior spinal artery, and lack of arachnoiditis, it is unlikely that this was a direct toxic action of the drugs on the cord.

A further possible cause is the vasoconstrictor action of adrenaline. The solution used during the anaesthetic procedure contained 1 in 300,000 adrenaline. Ruben *et al.* (1948) reported the spinal anaesthetic effects in the human following the use of vasoconstrictor substances alone. Priddle and Andros (1950), using adrenaline solution of 1 in 2,500 dilution, produced hypoaesthesia in the saddle area

following intrathecal injection. The explanation may be that this is an anoxic effect due to the vasoconstrictor action. However, those workers suggest that adrenaline itself has a direct effect on nerve conduction, and Forbes *et al.* (1933) and Fog (1939) showed that there was no arteriolar constriction following direct application of adrenaline to the pia mater. Nevertheless, the clinical and pathological findings of nervous damage confined to the anterior spinal artery distribution strongly suggest that some block, albeit transient, occurred in this arterial supply, and we believe that adrenaline could have caused such a transient block.

It is appropriate at this stage to discuss briefly the significant points concerning the arterial anatomy in the region. The cord derives its supply from three vessels, one anterior and two posterior. The anterior spinal artery arises as a branch from each vertebral artery. These unite at the level of the foramen magnum to form one vessel, which runs down the whole length of the cord in the midline. This vessel, through multiple small branches, supplies the lateral column and the anterior grey and white columns. The posterior pair of arteries arise from the posterior inferior cerebellar or from the vertebral arteries, and run down the whole length of the cord in relation to the posterior nerve roots supplying the posterior third of the cord. The anterior spinal artery is virtually an end-artery receiving significant collaterals only at the level of T1 and T11. The posterior spinal arteries in contrast have numerous collateral vessels freely anastomosing over the posterior part of the cord. It is obvious that interference with the blood supply derived from the anterior artery will give rise to ischaemic changes in the anterior two-thirds of the cord; whereas occlusion of the posterior vessels is less likely to produce permanent changes because of their free anastomosis.

The syndrome of anterior spinal artery thrombosis was first clinically diagnosed by Spiller (1909). Since his description many cases of this syndrome have been reported. The following aetiological factors have been blamed: interference with the blood supply through aortic compression, thrombosis, aneurysm and coarctation, syphilitic thrombosis, arteriosclerosis, and simple vascular spasm; as well as trauma, both direct and indirect, and compression due to tumour or disk (Steggmann, 1952; Peterman *et al.*, 1958). Still, there are numerous reports of cases where no causative factors were found.

The lesion produces a definite clinical picture of destruction in the area supplied by this anterior spinal artery. Most commonly the areas affected have been the lower cervical and the thoraco-lumbar regions. Our case was typical of this syndrome, and further elaboration is unnecessary.

Summary and Conclusions

A case of the anterior artery syndrome following epidural anaesthesia is presented.

We have discussed the possible causes of the anterior spinal artery syndrome in this case, and have come to the conclusion that no single factor was responsible. We believe that there are possibly two causes: firstly, the relative hypotension imposed on the patient's already failing peripheral circulation; and, secondly, the vaso-failing peripheral circulation. From the histological findings that thrombosis had not occurred in this artery, we have to assume, therefore, that the occlusion was of sufficient transient nature. Unfortunately, this was of sufficient duration to produce permanent changes in the anterior part of the cord due to ischaemia. His arterial supply was probably already decreased owing to his heart failure, and therefore interference with this supply was disastrous. Finally, it should be mentioned that cases of spontaneous occlusion of the anterior spinal artery have been reported and that, although unlikely, this might have been purely coincidental.

We thank Professor R. S. Pilcher for permission to publish this case and for his criticism and advice. Also we are indebted to Dr. Massey Dawkins for his helpful discussion. We thank Dr. W. Blackwood for his interest in the sections of the cord and Dr. D. H. Mills, of Ashford Hospital, for details of the patient's previous history.

NEUROLOGICAL COMPLICATIONS OF EPIDURAL ANAESTHESIA

BY

J. BRAHAM, M.C., M.D., M.R.C.P.

AND

ALMA SAIA, M.D. (Bucharest)

Neurological Department, Tel-Hashomer Government
Hospital, Israel

Epidural anaesthesia is generally regarded as being safe, easy to carry out, and free from complications. Many authors, in reviews of its use in thousands of cases, record very low mortality and morbidity. The technique of the injection involves the introduction of a lumbar-puncture needle between two spinous processes into the epidural space. In this situation a negative pressure exists, as demonstrated by the suction effect upon a drop of saline placed on the hilt of the needle. 2 ml. of 2% procaine solution is injected, and if during the next 10 minutes no reaction occurs a further 25–30 ml. is introduced.

Two cases are described in which neurological complications of a very serious nature appeared after epidural anaesthesia with the technique described above.

Case 1

A 26-year-old housewife had a caesarean section at another hospital four months previously, and because of a history of bronchial asthma epidural anaesthesia was decided upon. No untoward incidents were noted at the time of operation, but the same day she complained of headache and double vision, the latter passing off in a few hours. Headache and a feeling of intracranial pressure persisted for a few weeks, and at this time the patient noticed gradually increasing difficulty in walking. Weakness in the legs, first right and then left, became progressively more pronounced until a few weeks later she was quite unable to walk. Impairment of sphincter control followed some weeks later and became complete. She was readmitted to hospital, where lumbar puncture revealed partial manometric block. On myelographic examination the oil column was held up at D11.

The patient was transferred to this hospital and showed paralysis of the lower limbs, complete apart from feeble flexion of the right knee. The muscles were hypotonic, the right knee-jerk and abdominal reflexes were absent, and there was left bilateral ankle clonus; sensation, both

superficial and deep, was much impaired up to D 11. The bladder was paralysed, with retention of urine. In the hope that the cause of the paraplegia might conceivably be a local constrictive arachnoiditis at the level of the myelographic block, the patient was transferred to the neurosurgical department. Laminectomy at D 11-L 1, performed by Dr. Herzberger, revealed gross arachnoiditis, the cord being embedded in an opalescent jelly-like mass which extended as far as could be seen cranially and caudally. The condition of the patient was not influenced by the decompression, and she remained permanently crippled.

Case 2

A 66-year-old man was admitted for surgical treatment of vesical calculi. Five years previously he had undergone a spinal operation for a tumour at D 12, which proved to be a chordoma. His symptoms at the time were pains in the back and legs, and these were relieved by the operation. Up to the time of this second admission he had been entirely free of any complaints referable to the lower limbs and there were no objective neurological residua. Transurethral lithotomy under epidural anaesthesia passed off without incident.

A month later a second-stage operation was performed with transurethral resection of the prostate, again under epidural anaesthesia (L 2-3). The patient was seen in consultation on the following day because power in the legs had failed to return. He was found in good general condition, with paralysis of ilio-psoas and quadriceps muscles bilaterally; muscles below the knees were active. Deep reflexes were absent and sensation was reduced below the level of L 3. With this distribution of paralysis it was thought less likely that there had been inadvertent intrathecal injection than that for some reason the roots at the level of the injection had failed to recover from the anaesthesia. During the succeeding weeks there was only minor improvement until the patient died from cardio-pulmonary complications.

At post-mortem examination the remains of a nodular growth were seen at D 12 with an intrathecal extension the size of a pea. Considering the time relationship as outlined above, it was not thought that this tumour played a part in the production of the post-operative paralysis.

Discussion

The mechanism of production of the cord changes described above must remain to some extent speculative. Although sepsis cannot be ruled out, it is probably an unlikely explanation. In Case 1 there was nothing to suggest an acute post-operative meningitis; in Case 2 the complications were immediate, but limited to the anatomical segments innervated from the level of the injections. Taking into consideration the headaches and double-vision experienced by the first patient on the day of operation, it seems difficult to exclude the likelihood that the arachnoiditis and cord changes were a direct expression of a chemical meningo-myelopathy resulting from inadvertent injection of the anaesthetic into the subarachnoid space. Since complications of this nature are known (Payne and Bergentz, 1956) to follow deliberate intraspinal anaesthesia where total quantities of only 40 mg. of procaine are employed, it is not unreasonable to suppose that they may result from the introduction of some portion of the total of 500 mg. commonly employed in epidural anaesthesia. The clinical course of the case described by Payne and Bergentz resembles very closely that of our Case 1. Progressive paraplegia began seven days after the anaesthesia and became complete in two weeks. These authors quote experimental work on dogs which demonstrated the appearance of local arachnoiditis following spinal anaesthesia in clinical doses. Haxton (1956) mentions an experience of his own in which an intrathecal injection of phenol was unwittingly given when the intention was to place the needle paravertebrally, let alone epidurally.

Local hypersensitivity of nerve roots to the anaesthetic reagent or chemical changes or impurities may perhaps be invoked to account for the persistent paralysis in our second case.

General hypersensitivity to the anaesthetic agent would seem to be an unlikely explanation, as a reaction of a more widespread nature might be expected. In this connexion it is of no small interest that in the course of our investigation into the complications of epidural anaesthesia prompted by the above experiences it was discovered that the only two cases of cardiac arrest during anaesthesia which had occurred in this hospital happened while this method was being employed and before the operation itself had started.

Both patients were in good general health and were admitted for elective operations. In one, 15 ml. of anaesthetic was injected, when the heart suddenly stopped. In the second it was thought that a portion of the anaesthetic may have been introduced intrathecally. The needle was partially withdrawn and the anaesthesia proceeded with, as there were apparently no reactions; however, a few minutes later, as the skin was being incised, the pulse stopped. Cardiac massage succeeded in restoring the pulse in both cases, and one patient made a reasonable recovery in the course of some weeks; the other died in coma. In these two cases one may postulate the existence of hypersensitivity to procaine, though a reaction to the flooding of the cerebrospinal fluid with large quantities of anaesthetic cannot be ruled out.

Though the numerical incidence of complications following epidural anaesthesia as seen in this hospital is low (4 out of 200 lumbar and several hundred sacral injections) their seriousness and their tragic consequences suggest that this method should be employed only after very careful consideration. Although this method is claimed to be safe, we cannot be sure that all complications are indeed brought to light or even thought of when they are of delayed onset. It seems that Walshe's (1956) criticisms of intrathecal anaesthesia may be equally pertinent when applied to epidural anaesthesia.

Summary

Neurological complications are described in two patients following epidural anaesthesia: they are believed to have been due to a local chemical meningo-myelopathy or neuropathy.

Reference is made to two cases of cardiac arrest attributable to this technique.

The Third International Congress of Photofluorography was held in Stockholm last month under the presidency of Professor CARL WEGELIUS. It was attended by 600 delegates from all over the world. The papers read at the Congress gave clear evidence that here is a field in a ferment of activity. Important advances such as alkali halide intensifying screens and new methods of film processing suggest that up to a tenfold reduction in received radiation may be expected from technical innovations. With modern coning and filtering of the x-ray beam the dose to the skin and gonads in taking a single chest film can be reduced to less than the weekly permitted safe dose for radiographers who spend their whole working lives exposed to x-radiation, while image intensification can increase the brightness of the screen picture a thousand times. This allows screening at very low radiation levels, a degree of brightness that makes dark adaptation unnecessary, and the making of permanent multiple or cine photographic records of physiological or pathological functions for analysis at leisure in "slow motion." A special edition of *Excerpta Medica* summarizes most of the papers presented at the Congress.

THROMBOSIS OF THE MAJOR PULMONARY ARTERIES

BY

J. ALAN S. AMOS, M.D., D.T.M.&H.
Senior Registrar in Pathology, St. George's and
Southampton Group Hospitals

The clinical syndromes of pulmonary artery thrombosis are less well known than those of acute pulmonary embolism. Thrombosis may involve the secondary and tertiary branches, or the main right or left arteries and pulmonary trunk. Thrombosis of these larger vessels is uncommon. It is, nevertheless, being increasingly reported as a cause of striking clinical deterioration in a wide variety of predisposing illness (Ring and Bakke, 1955).

Pathogenesis

There are two main ways in which such thrombi can arise: (a) primary thrombi, and (b) secondary to pulmonary emboli. Carroll (1950), Hanelin and Eyer (1951), and Magidson and Jacobson (1955) have reported groups of cases, many showing a history of embolism or leg-vein thrombosis. The frequent finding of thrombi in the right heart or systemic veins led Brenner (1935) and Belt (1939) to conclude that most pulmonary artery thrombi are embolic in origin. Belt demonstrated by necropsy studies the sequence of changes which may follow embolism. He cites the elongated shape and characteristic mode of attachment of the thrombus, the lack of local vascular lesions, and the finding of thrombi of similar age in the peripheral veins as evidence for an embolic origin of many of these thrombi.

In six of seven cases described by Keating *et al.* (1953) there was evidence that the thrombi had arisen *in situ*, there was evidence that the thrombi had arisen *in situ*, either from the direct involvement of the vessels by primary lung disease, or as a result of disease of the vessels themselves. All their patients died in acute cor pulmonale. Advanced tuberculosis and anthracopulmonale. Advanced tuberculosis and anthracopulmonale were predisposing illnesses in the patients reported by Savocool and Charr (1941), who were able to trace the thrombosed vessels into the affected areas. The condition may develop in congenital and acquired heart disease, pulmonary hypertension and the altered dynamics of vascular shunts being predisposing factors. Thus, Kampmeier (1934) describes the condition with mitral stenosis, while interventricular septal defect (Bryson, 1949), cor triloculare (Cunningham, 1948), Fallot's tetralogy (Rich, 1948; Ring and Bakke, 1955), and persistent ductus arteriosus (Whitaker, Heath, and Brown, 1955), and in particular atrial septal defect (Bedford *et al.*, 1941; Trounce, 1953; Campbell, Neill, and Suzman, 1957) may be associated with widespread pulmonary artery thrombosis. When heart disease is present a vicious circle may develop in which thrombosis further increases the strain on the heart and predisposes to further extension of thrombosis.

Other factors can play a part in pathogenesis. Malignant disease may directly involve the pulmonary arteries, or cause widespread obstruction by multiple tumour emboli (Brill and Robertson, 1937). Multiple venous thromboses in association with malignant disease may involve the pulmonary vessels and progress despite adequate anticoagulant therapy.

Abnormal blood conditions such as primary or secondary polycythaemia (Hodes and Griffith, 1941; Carroll, 1950), sickle-cell disease (Yater and Hansmann, 1936), and cryoglobulinaemia (Cugudda, 1952) will at times predispose to pulmonary artery thromboses.

Although the pathogenesis of thrombosis is usually established by consideration of the post-mortem appearances together with the clinical findings, the distinction between post-embolic and autochthonous thrombosis may not be possible even at necropsy.

Present Investigation

Now that prolonged anticoagulant therapy is possible, it is important to recognize the syndromes of chronic thrombotic obstruction of the pulmonary vessels during life. The purpose of this paper is to present the findings in 19 cases in which thrombosis of the major pulmonary arteries was confirmed at necropsy. They illustrate the wide variety of predisposing illness, the varying factors in pathogenesis, and the types of clinical illness which result.

Sixteen of the cases were chosen from 1,673 consecutive post-mortem examinations carried out at St. George's Hospital, London, during the period January, 1952, to July, 1956. Three were observed subsequently. In all cases thrombosis affected the pulmonary trunk or the main left or right branches proximal to the hilum. Patients in whom major clinical embolism was the immediate cause of death were excluded. In the patients reported here, at least three weeks had elapsed since any major embolic episode; at necropsy the thrombi were organized and adherent in all but three of the cases.

Clinical Features

The ages in the present series range from 22 months to 78 years, 14 patients being over 50 years of age at the time of death. The clinical and pathological findings are summarized in the Table. Cases are divided into two main groups, Figs. 1, 2, and 3 illustrating the appearances and extent of the thrombotic obstruction of post-embolic and autochthonous thrombosis.

Group 1.—In six patients there was a history of frank pulmonary embolism during the preceding three months. In two further cases pulmonary embolism produced only minimal clinical changes, their possible significance in the resulting illness being recognized only in retrospect.

Group 2.—Of the nine examples of presumed *in situ* thrombosis, six had chronic heart disease and three emphysema. There was no definite history of thrombosis of the leg-veins, nor did necropsy reveal thrombi in the peripheral veins of similar age to the pulmonary artery thrombi. In the remaining two patients there were no progressive cardio-respiratory symptoms; at necropsy the pulmonary thrombi were pale, friable, and only lightly adherent. Their appearances suggested that they had formed terminally.

FIG. 1.—Case 1. Post-embolic thrombosis of the pulmonary arteries. A major embolic episode occurred three weeks before death. Smooth adherent thromboembolus occludes much of the lumen of both the right and left pulmonary arteries. Many of the secondary branches are affected.

The most frequently observed clinical features were increasing dyspnoea, cyanosis, and right heart failure. Dyspnoea was severe in 14 of the 19 cases, being often progressive and intractable, and at times proportionately more severe than the clinical and radiological findings suggested. Nevertheless, both dyspnoea and cyanosis were on occasion absent or minimal.

The cardio-respiratory symptoms of many of the underlying conditions make it difficult to appreciate any additional changes due to pulmonary artery thrombosis. A review of the clinical findings in this series did, however, reveal a number of features thought to be associated with the increasing thrombotic obstruction. These were the sudden onset of acute cor pulmonale with striking coldness of the extremities (Cases 9, 10, 11, and 14), paroxysmal epigastric pains (Case 11), the development of a prolonged generalized systolic murmur (Case 5), the onset of visible pulsations in the pulmonary area with greater accentuation of the second sound (Case 15), and possibly the development of paroxysmal cardiac arrhythmias (Case 12).

Electrocardiograms were taken in 11 patients and serial records were available in nine of these. There were no constant changes, the findings in general remaining those of the underlying conditions.

In 15 of the cases radiographic examination was made during the last three weeks of life, serial records being made in nine. In one of the two cases in which screening was carried out there was expansile pulsation of the proximal portions of the dilated right pulmonary vessels which diminished abruptly distally (Case 14). The most frequent finding (11 patients) was conspicuous enlargement of the pulmonary vessel shadows. In only three of the cases could progressive ischaemic changes of the peripheral lung fields characteristic of pulmonary artery obstruction be recognized. In some cases this was because the lung fields were obscured by the changes of effusion or infarction; in several, however, no changes of pulmonary artery obstruction were detected even though serial radiographs were compared. A further change noted (Case 13) was that of increasing accentuation of the pulmonary vessel outline due to diminished pulsation of the affected area.

The patients showed three types of clinical course. Cases 1, 2, 3, 4, 5, and 8 showed episodes of clinical pulmonary embolism, often repeated, with subacute cor pulmonale. In Cases 9, 10, 11, and 14 the post-mortem appearances suggested that the pulmonary artery thrombi had been present for some weeks, since they were well organized and firmly adherent. Nevertheless, few symptoms had resulted until the patients suddenly developed acute cor pulmonale. A gradually worsening chronic cor pulmonale was observed in one patient only (Case 6). Death occurred from other causes before cardio-respiratory symptoms were at all severe.

The present findings also support the observations that the right artery is more often affected than the left (Savacool and Charr, 1941). Even when thrombosis is bilateral, they point out that older lesions may often be identified in the right branches with recent extension to the left. They suggest that this may be related to the differing anatomy of the blood vessels at the lung roots.

Diagnosis has seldom been established during life. The condition may, however, be strongly suspected when there is a history of venous thrombosis of the legs followed by cardio-respiratory symptoms. That the time interval before cardio-respiratory symptoms may be measured in years is illustrated by a number of striking case reports (Means and Mallory, 1931; Covey, 1943; Madigson and Jacobson, 1955). In none of the present cases did the time between leg-vein thrombosis and embolic symptoms exceed three months. We have under treatment a further case in which subacute cor pulmonale has developed three and a half years after deep femoral vein thrombosis and in which radiological changes suggest pulmonary artery obstruction. It is well recognized that the clinical features of pulmonary embolism may be minimal; their significance was overlooked in Case 6 of the present series.

The condition may also be suspected when there is unexplained deterioration in any of the known predisposing cardiac or respiratory illnesses. The present findings support the view that *in situ* pulmonary artery thrombosis is particularly liable to occur when local vascular disease is severe, advanced vascular pathological changes being present in seven of the nine examples.

There may be changes in the physical signs. Changing heart signs were noted in three patients and epigastric pains in one patient. Severe attacks of epigastric pain were a striking feature in the patients studied by Middleton (1943) and in two reported by Magidson and Jacobson (1955). Syncopal attacks related to acute embolic episodes may be observed (Ball *et al.*, 1956).

The condition may first be suspected radiologically. The characteristic changes have been described by Westermarck (1948). These include right-sided heart enlargement, dilatation of the pulmonary artery proximal to the obstruction, with alteration of the vessel contour, and increased trans-

FIG. 2.—Case 13. *In situ* thrombosis of the pulmonary arteries. The arteries contain grey adherent laminated thrombus. Many of the peripheral vessels are occluded.

FIG. 3.—Case 11. Bilateral thrombosis of the pulmonary arteries. The relationship of the thrombus to atheroma of the vessels is seen in the right branch (below).

lucency of the lung fields distal to the obstruction. Keating *et al.* (1953) draw attention to the accentuation of the vessel outline due to diminished pulsations of the affected area. Three of the fifteen patients in the present series who had radiographs showed such changes, and screening was of assistance in a further case. Frequent and comparable radiographs in cases of cor pulmonale are of obvious value in the detection of the changes.

Electrocardiography did not suggest the diagnosis in the present cases, although the change to right-axis deviation from pre-existing left-axis deviation may be striking (Keating *et al.*, 1953).

The increasing use of angiography may confirm the diagnosis more often in the future. Obstruction to the major arteries has been demonstrated by this means (Carroll, 1950), and to the segmental vessels (Aitchison and McKay, 1956).

The present cases illustrate the variability of clinical effects attributable to massive pulmonary artery thrombosis. That these may be minimal is shown in Cases 6, 7, 8, and 18. This is in accord with evidence that in the experimental animal much of the pulmonary circulation may be obstructed without the development of progressive symptoms (Gibbon, Hopkinson, and Churchill, 1932), and with the necropsy findings in Cases 9, 10, 11, and 14, when virtually no progressive symptoms occurred until the patient suddenly developed acute cor pulmonale.

The most frequent clinical course was that of repeated embolic episodes or of an overwhelming acute cor pulmonale. Only one patient in the present series showed a slowly progressive chronic cor pulmonale. This type of illness may be the least frequent of the clinical syndromes of pulmonary artery thrombosis.

Discussion

Clinical and Pathological Features of 19 Cases of Pulmonary Artery Thrombosis

Case No.	Age	Sex	History	Duration of Recent Symptoms	Predisposing Conditions	Thrombosis Site	Heart Weight	Lung Vessels		Lung Infarction
								Major Artery Atheroma	Arterioles	
Group 1. Following Pulmonary Embolism										
1	48	M	Post-operative embolism. Femoral-vein ligation. Increasing dyspnoea and haemoptyses	3 weeks	Embolism	Bilateral	—	—	—	++
2	56	M	Cardiac infarction — progressive dyspnoea and haemoptyses. Death in congestive failure	9 "	Antero-septal infarction —mural thrombi	Left branch	720 g.	—	—	++
3	66	M	Venous thrombosis right leg. Pulmonary embolism. Spastic weakness right arm. Thrombosis left leg	5 "	Unsuspected hypernephroma. Multiple venous thromboses	Right "	540 g.	—	Intimal thickening	++
4	66	M	Venous thrombosis left leg. Pulmonary embolism. Left cephalic vein thrombosis. Recurring pleural effusion	3 months	Carcinoma left bronchus. Multiple venous thromboses	" "	370 g.	—	—	—
5	45	M	Emphysema and cor pulmonale 3 years. Leg-vein thrombosis and embolism	3 weeks	Recent embolism left branch—old thrombosis of right branch	Bilateral	450 g.	++	Severe arterio-sclerosis	+
6	69	F	"Feverish chill" followed by dyspnoea on exertion and persistent tachycardia	3 months	Embolism. Death from peritonitis due to perforation	"	360 g.	—	—	—
7	73	F	Hypertensive heart failure. Transient left apical chest pain. Re-admitted after insulin overdosage	3 "	Hypertensive heart disease. Diabetes. Prolonged coma	Left branch	420 g.	—	Intimal thickening	+
8	70	M	Fractured neck of femur—pinned. Increasing right hemiplegia post-operatively	3 weeks	Polycythaemia rubra vera. Hypertension	Bilateral	480 g.	—	"	+
Group 2. In Situ Thrombosis										
9	64	M	Chronic bronchitis and emphysema. Sudden acute cor pulmonale	24 hours	Emphysema	Right branch	330 g.	++	—	+
10	62	F	Parkinsonism 3 years. Kyphoscoliosis. Slight dyspnoea on exertion. Sudden acute cor pulmonale	8 weeks	"	Bilateral	380 g.	++	Severe arterio-sclerosis	+
11	62	M	Chronic bronchitis, worse 1 year. Recent epigastric pains. Acute cor pulmonale	48 hours	"	"	—	+	"	?
12	26	M	6 years' increasing dyspnoea. Recent right lower lobe "pneumonia." Congestive failure with fibrillation	3 months	Persistent ductus. Aortic coarctation	Right branch	650 g.	++	Moderate arterio-sclerosis	+
13	62	M	6 years' auricular flutter. Well controlled until 3 months before death	3 "	Atrial septal defect. Mural cardiac thrombi	Bilateral	750 g.	++	Severe arterio-sclerosis	++
14	52	M	Increasing dyspnoea with paroxysmal fibrillation. Sudden acute cor pulmonale	7 "	Lutembacher's syndrome	Right	630 g.	++	"	++
15	39	F	16 years' mitral stenosis. Episodes of congestive failure	2 weeks	Mitral stenosis	Bilateral and pulmonary conus	555 g.	+	Arteriosclerosis. Fibrinoid necrosis. Elastic fragmentation	++
16	68	F	6 months' increasing dyspnoea. Acute cor pulmonale	6 months	" "	Bilateral hilar. Thrombi red and not organized	600 g.	+	Severe arterio-sclerosis	+
17	68	F	2 years' congestive failure and fibrillation. Sudden acute cor pulmonale	3 days	" "	Left	600 g.	+	Moderate arterio-sclerosis	+
Group 3. Other Cases										
18	22 mths	M	3 days' fever and petechial rash	3 days	Pneumococcal septicaemia. Mastoiditis. Thrombus pale and not organized	Left branch	—	—	—	+
19	78	M	Cerebral vascular accident 3 weeks before death	3 weeks	Cerebral infarction. Prolonged coma	Bilateral	300 g.	—	—	+

Summary and Conclusions

Thrombosis of the major pulmonary arteries is being increasingly recognized as a complicating event in a variety of illnesses.

The clinical and pathological findings are summarized in 19 further examples. In eight cases thrombosis was consequent on previous pulmonary embolism, in nine the findings suggested that autochthonous thrombosis had occurred. In two cases the pathogenesis was not established with certainty.

The pathogenesis and clinical effects are briefly discussed. Many of the patients have severe disease of the heart or lungs. The variability of the clinical effects attributable to pulmonary artery thrombosis is stressed. In this series they ranged from minimal changes to sudden intractable right heart failure.

Although the clinical changes are often masked by the underlying illness, the diagnosis may be suggested by a history of thrombophlebitis or embolism, by the occurrence of new and unexpected clinical signs and symptoms in the course of one of the predisposing illnesses, and on occasion by the radiological appearances.

Some patients show an illness characterized by recurrent embolization; in others the presence of thrombotic obstruction is virtually symptomless until the onset of acute cor pulmonale. Less frequently, the thrombosis gives rise to a chronic cor pulmonale.

Thrombosis of the major pulmonary arteries may therefore have to be considered in the diagnosis of any case of acute, subacute, or chronic cor pulmonale.

I thank Dr. D. Dexter for his help and Professor T. Crawford for his assistance and advice in the preparation of the paper. Dr. D. Teare kindly allowed access to his material and records in Cases 16 and 18.

"Extra Care Stops Falls" is the slogan adopted by the Royal Society for the Prevention of Accidents for this year's National Industrial Safety Week, which is to be held from September 29 to October 4. The theme forms the basis of a nationwide campaign directed to both managements and workers with the object of reducing the toll of industrial accidents, and particularly those associated with falls of persons. In 1956, 22,548 persons were absent from work as a result of injuries following falls, equal to 14.1% of all reported industrial accidents.

ANAEMIA OF UNCERTAIN ORIGIN
IN INFANCY

BY

R. G. HENDRICKSE, M.D., M.R.C.P.Ed.

Lecturer, Department of Paediatrics

AND

M. A. R. KING, M.B., Ch.B.

Late Registrar, Department of Pathology

University College Hospital, Ibadan, Nigeria

Severe anaemia in infancy and childhood is often seen at University College Hospital, Ibadan, Nigeria. In most cases anaemia occurs in association with conditions such as kwashiorkor, cancrum oris, tuberculosis, and chronic sepsis. Sick-cell anaemia is also relatively common. However, many patients present, especially during the first two years of life, with severe anaemia unassociated with other recognizable diseases and not due to the sickle-cell gene. There has been much speculation about the aetiology and pathogenesis of anaemia in this latter group, and malignant tertian malaria and dietary deficiencies (chiefly protein and iron) have long been regarded as the most likely causal factors. Little has been done, however, to verify these speculations. We report here the results of investigation and treatment of 24 of these cases selected from 85 similar cases which occurred among 1,318 admissions to the children's ward during the period October, 1955, to June 30, 1956.

Case Selection.—In a busy ward with a very rapid turnover of cases, one cot was set aside and used exclusively for the investigation of children under 2 years of age with severe anaemia (haemoglobin, 5.9 g./100 ml. or lower). Sick-cell anaemia and anaemia complicating some other illness were excluded. The 24 cases presented were those who were admitted into this cot.

Methods

Besides routine clinical examination the following were done: Tuberculin-testing by the Heaf technique was routinely performed and the majority of children had an x-ray examination of the chest and wrists. Haemoglobins were estimated, using Keeler M.R.C. grey wedge photometers (100% = 14.8 g./100 ml.). Thin blood films were stained with Leishman's and thick films with Field's stain. Supravital preparations, stained with brilliant cresyl blue (dried alcoholic solution), were made for reticulocyte determination (Whitby and Britton, 1953). Bone marrow was obtained by iliac crest puncture (Rubinstein, 1950), and smears were stained by Leishman and also by May-Grünwald-Giemsa. Differential marrow counts were made using the terminology of Dacie and White (1949) and red-cell maturation curves constructed (Pontoni, 1936). Serum protein estimation was performed by the biuret method, using a photoelectric colorimeter. Results were checked monthly against Kjeldahl. Liver-function tests consisted of thymol turbidity, zinc sulphate turbidity, alkaline phosphatase, and serum bilirubin, all performed with standard techniques. In four patients the serum cholesterol and in two the total serum lipids were estimated. Plasma volume estimation based on the single-injection technique of Chinard (1951) using Evans blue was performed on four patients before and after treatment. Sickling of the red cells was tested for by using a freshly prepared 2% solution of sodium metabisulphite. Cases showing sickling had samples of haemoglobin submitted for paper electrophoresis.

Routine Management

On admission, after blood and bone-marrow samples had been collected, each patient was given 200 mg. of "nivaquine" (150 mg. of chloroquine base) twice daily for three days. The only exception was Case 23, in which 25 mg. of mepacrine was given twice daily for three days. While in hospital all patients were fed by their mothers on food supplied only by them. We withheld comment on their feeding regimes. This course was decided on in order to eliminate alteration in the diet as a factor when assessing the results of treatment. Haemoglobin estimations and blood reticulocyte counts were done as often as possible. Blood transfusions were administered when it was considered that delay would jeopardize the patient's ultimate recovery. No haematinic was administered to any patient while in hospital, and indeed only one patient received ferrous sulphate, while attending the follow-up clinic. Complications were handled as circumstances warranted. After discharge patients were referred to a special follow-up clinic.

Results

Table I sets out the principal symptoms and signs, haemoglobins on admission, sickling, white-cell counts, and complications encountered.

History.—The average age of the patients was 9½ months (range 4 to 21); only two were over 12 months. There were 16 males and 8 females. The average duration of symptoms was 8½ days (range 1 to 60). All but three patients presented with fever; cough was present in 17 and vomiting in 10.

Diet.—With one exception (Case No. 1) all the patients were breast-fed. (Breast-feeding is almost universal in Ibadan during the first two years of life.) The majority in addition received a carbohydrate supplement in the form of "pap" (maize), "amala" (yam flour), and bread. Six of the mothers included a small ration of powdered milk in the

dietary, and one of these also gave her child orange juice daily.

General Condition on Admission.—Despite severe anaemia 12 cases were in good condition and four fair. The contrast between haemoglobin level and apparent well-being was striking in many of these children. Fig. 1 shows Case 24 soon after admission when his haemoglobin was only 3.8 g./100 ml. It will be seen that he is bright-faced and apparently in robust health. On the other hand, Cases 1, 3, 5, 13, 15, 19, and 23 were very ill on admission and their general condition caused anxiety. There appeared to be no constant relation between haemoglobin level and the degree of illness manifested.

Nutrition.—The majority were seen to be underweight, some grossly, when compared with standard weight curves for British and American children. The comparison is not valid because of vast social, economic, environmental, and genetic differences in the groups compared. Walters (1956), working in Ilobi, a typical Yoruba village in Western Nigeria, found that the average weight of normal children under 5 years of age was about 20% below that of English

FIG. 1.—Case 24. The haemoglobin was 3.7 g./100 ml. when this photograph was taken.

children of the same age. Assessing our patients by standards familiar to us from work in the children's department at University College Hospital, Ibadan, most were classified as "within normal limits." Three patients (Cases 1, 6, and 19) showed evidence of mild protein malnutrition.

Cardiovascular System.—Nothing abnormal in the heart could be detected in 12 of our cases. The remainder all had apical systolic murmurs, and, in addition, Cases 1, 7, 13, and 18 showed enlargement of the heart, and in Cases 2, 7, 13, and 20 there was apical gallop rhythm. Case 13 was in congestive cardiac failure on admission. All cardiac signs disappeared on correction of the anaemia.

Abdomen and Chest.—The liver was palpable in 16 cases, and varied in size between 1 and 3 fingerbreadths below the costal margin. The spleen was enlarged in 19 patients, varying from "just palpable" to 4 fingerbreadths below the costal margin. The consistency of the organ was firm and in some patients it appeared to be tender. In spite of the frequent history of cough, only four patients showed evidence of mild respiratory infection. There were no positive tuberculin reactors. Cases 9, 11, and 18 were complicated by non-specific gastro-enteritis that developed in hospital, and were treated with parenteral fluids.

Haematological Findings

As already stated, only those patients with haemoglobin levels of 5.9 g./100 ml. (40%) or lower were included in the investigation. The blood-film appearances are summarized in Table II. It will be seen that in most films the cells were normochromic or slightly hypochromic, and that anisocytosis, poikilocytosis, and polychromasia were frequent findings.

Malarial parasitaemia was found in 13 cases, in all of which the parasite was *Plasmodium falciparum*. The initial reticulocyte count varied from 1% to 28% of total red cells, and in most the count was 5% or more. There appeared to be no relation between reticulocytosis and parasitaemia. The bone marrow showed a normoblastic hyper-

FIG. 2.—Anaemia of infancy presumed to be malarial. Bone-marrow red-cell maturation curves.

plasia in all but one of the patients from whom successful smears were made. Case 6 showed a mildly macronormoblastic marrow. There was evidence of very active erythropoiesis, with a greatly reduced leuco-erythrocytic ratio (average 0.2:1; range 0.1–0.41:1) in all except Cases 13, 16, and 22, in which the ratio was within normal limits given by Dacie and White (1949)—namely, 0.56–2.67:1.

Bone-marrow maturation curves varied in pattern. Some cases showed a normal pattern with raised peaks, while others showed curves similar to those described for iron-deficiency and congenital haemolytic anaemias. Fig. 2 shows curves that were constructed for 12 cases in the series. Included for comparison are maturation curves after Dacie and White (1949) (Fig. 3).

Sickling tests were positive in Cases 11, 19, 21, and 22. Case 11 also had reduced osmotic fragility of the red cells. All four cases were, however, confirmed to be sickle-cell trait and not sickle-cell anaemia on paper electrophoresis of the haemoglobin.

The total white-cell count varied considerably, but in 9 of the 16 cases in which counts were done on admission the figure was below 12,000. Two of the remaining cases had counts over 20,000. The differential counts showed a polymorph preponderance in eight cases. Monocytes, many showing pigment granules, were conspicuous in the majority.

Plasma Volume Estimations.—We are indebted to Dr. H. Schneiden, of the department of physiology, for this investigation. Results of estimations done before and after investigation. Results of estimations done before and after a rise in haemoglobin level in four cases are given in Table III. It will be seen that in Cases 5 and 8 there was a fall in plasma volumes corresponding with a rise in haemoglobin. Case 6 showed no real change. Case 9 had the first test on the day before he contracted gastro-

T.T. = thymol turbidity. ZnSO₄ = zinc sulphate turbidity. * Liver function tests done after correction of the anaemia. Comment: The high degree of systemic lipaemia in Cases 3 and 4 probably interfered with accurate globulin determination. In both these patients the serum presented an opaque, creamy appearance.

enteritis and became dehydrated. This may in part account for the rise in plasma volume in the second reading.

Serum Proteins.—The average serum albumin level in 12 cases was 3.24 g./100 ml. (range 2.8 to 3.7) and globulin 3.62 g./100 ml. (range 1.8 to 6.8), giving an A/G ratio of 0.89 to 1. Cases 3 and 4 showed abnormally high globulin levels which were thought to be false values occasioned by a high degree of systemic lipaemia which was present in these cases and interfered with accurate globulin determination. Excluding Cases 3 and 4, the average serum globulin becomes 3.07 g./100 ml. and the A/G ratio 1.05 (see Table IV). In order to provide a comparison, we examined the blood of some healthy non-anaemic children seen at an

Comment.—The children selected for the above investigations were all well nourished and showed no clinical evidence of anaemia. Physical examination revealed no abnormality. Blood films of Cases WC/28, 319, and 324 were negative for malarial parasites. The remaining cases did not have blood films taken at the time the tests were performed. (The clinical assessment of these children was made by a senior paediatric consultant.)

infant welfare clinic. Results are shown in Table V. The average serum albumin was 3.05 g./100 ml. (range 1.5 to 3.8) and average globulin 2.9 g./100 ml. (range 1.8 to 4.2), giving an A/G ratio of 1.05 to 1. Edozien (1957) records the average results of serum protein determinations on 200 healthy adult Nigerians as follows:

Total protein	6.8 ± 0.4 g./100 ml. (5.8 to 7.5)
Albumin	3.6 ± 0.3 g./100 ml. (2.6 to 4.0)
Globulin	3.2 ± 0.4 g./100 ml. (2.5 to 4.0)
A/G ratio	1.12 (0.8 to 1.5)

It will be seen that all the patients with anaemia and all but one of the welfare clinic cases (WC/324) had serum proteins within normal limits for Nigerians.

Liver-function Tests

Thymol turbidity tests performed on 16 patients gave high readings (Table IV). The average value was 7.7 units (range 3.5 to 20.6). The zinc sulphate turbidity test performed on four patients gave an average reading of 14.5 units (range 7.5 to 22.5). Similar tests performed on the welfare clinic cases gave the following results (Table V): thymol turbidity, average, 4.3 units (range 0.6 to 8); zinc sulphate turbidity, average, 3.7 units (range 1.8 to 8). It will be seen that, while there was close agreement in the results of serum protein estimation in the two groups compared, the results of the flocculation tests differ. The zinc sulphate turbidity depends almost entirely on the gamma-globulin fraction of the serum, and is a relatively accurate index of the concentration of the gamma-globulin (Kunkel, 1947, and Discombe *et al.*, 1954, quoted by Edozien, 1957). It would therefore appear that there was a qualitative difference in the globulin fraction in the two groups, caused by an increase in the gamma-globulin in the anaemic children.

Estimation of the serum bilirubin in 15 anaemic patients gave an average value of 0.7 mg./100 ml. (range 0.2 to 1.9). Only three patients had values above the accepted upper limit of normal. Results on six welfare clinic cases gave

an average of 0.3 mg./100 ml. (range 0.15 to 0.5). Serum alkaline phosphatase levels tended to be high in both the anaemic and the non-anaemic children seen in the welfare clinic. Three children in the latter group gave readings of 70.28, 75.9, and 98.6 K.A. units respectively. The explanation might be that these children had rickets, a not uncommon finding in Ibadan, but the possibility of a laboratory error cannot be overlooked. (These three tests were done on the same day).

Response to Treatment

There were two deaths in the series; both occurred within the first few hours after admission. Case 13 was desperately ill on admission and thought to be in cardiac failure.

Transfusion
--- Reticulocytes
— Haemoglobin (100% = 14.8 g.)
+ Malarial Parasites found on admission
■ Nivaquine
□ Mepacrine

FIG. 4.—Anaemia of infancy presumed to be malarial. Haemoglobin and reticulocyte response to treatment.

She was given 50 ml. of packed cells and appeared to stand the transfusion well. Three hours later she was given an intramuscular injection of 200 mg. of nivaquine, and died shortly after. Case 15 was admitted with a haemoglobin level of 3.7 g./100 ml. and was in very poor general condition but showed no evidence of cardiac failure. He was transfused slowly and given 80 mg. of nivaquine by intramuscular injection but died shortly after. In neither case were we able to obtain a necropsy, nor was the exact cause of death determined, but in both we suspected that the injection of nivaquine might have been causally related. They were, however, both very anaemic and very ill and the risks of transfusion in such cases are considerable. Despite the very large oral doses of nivaquine used in this series and in many other patients, we have not observed any toxic effects when the drug is given by this route, but we have been alarmed on several occasions at sudden collapse occurring within minutes of an injection of nivaquine in anaemic infants not otherwise ill.

Fig. 4 shows the response of haemoglobin and reticulocytes to treatment over 40 days in 20 cases. (Cases 3 and 12 are shown separately on Fig. 5.) It will be seen that in all the untransfused patients the haemoglobin rose steeply after a lag period of up to seven days. In some patients there was a slight initial fall in haemoglobin. In Cases 2, 5, 6, 9, 21, and 24 the rise in the haemoglobin was sustained at the rate of 0.3 to 0.4 g./100 ml. (2-3%) for 14 to 21 days, reaching levels of 10.36 g. (70%) after about 21 days. Cases 20 and 22 appear to have responded in a similar manner, but the records are short. Case 8 responded similarly, but the level did not rise above 8.14 g. (55%). The haemoglobin level in Case 19 pursued a more erratic course, rising to 8.6 g. (58%) by the 29th day and remaining at this level for six weeks, after which it rose to 10.66 g. (72%) without further treatment. Case 23 showed a slower but steady rate of increase of haemoglobin from 4.9 g. (33%) on the first day to 11.8 g. (80%) by the 75th day.

In most of the transfused patients the post-transfusion level of haemoglobin was maintained or it continued to rise. Cases 7, 10, and 17 show this well. Case 14 showed a fall from 9.6 g. (65%) after transfusion to 8.6 g. (58%) on the 40th day, but by the 56th day the haemoglobin had risen to 11.24 g. (76%).

Fig. 5 shows the result of a 200-day follow-up in Cases 3 and 12. Case 3 had frequent relapses (or reinfections) of malignant tertian malaria in spite of prolonged use of nivaquine and pyrimethamine (daraprim) orally. On two occasions after nivaquine had been given intramuscularly, blood films became negative, reticulocytes rose and then fell, and the haemoglobin rose. Possibly his mother had failed to give him his oral doses, but she seemed reliable, and attended regularly, and insisted that she had carried out our instructions. Notwithstanding the persistent parasitaemia and fluctuations in haemoglobin level, his weight showed a slow but steady rise except between the 60th and 70th days, when there was a fall associated with an attack of diarrhoea.

In Case 12 the haemoglobin level fell steadily after transfusion, when it was over

15 g., to 6.35 g. (43%) by the 102nd day. This fall was accompanied by return of malarial parasites in the peripheral blood film. Nivaquine was then given and the haemoglobin again rose to 12.72 g. (86%) by the 137th day. His weight showed a steady increase throughout. When parasites reappeared on the 150th day there was another fall in haemoglobin and weight. No treatment was given. The haemoglobin level became stationary at 10.95 g. (74%) and the weight at 18 lb. (8,165 g.), and both remained thus until the 218th day (not shown in Fig. 5). On the 250th day he had fever and was coughing, and the haemoglobin was found to be 8 g. (54%). Nivaquine was prescribed. On the 280th day, when he was last seen, his haemoglobin level was 10.36 g. (70%) and his weight 20 lb. 8 oz. (9,300 g.).

Reticulocyte response to nivaquine seemed to be of two types. The first, shown by Cases 1, 3, 4, 6, 9, 16, 17, 18, 19, 20, and 21, is typified by a peak about seven days after start of treatment, and conforms to Fairley's (1934) description of a reticulocyte crisis following administration of quinine in malaria. The second type, seen in Cases 2, 5, 7, 8, 14, and 23, consists of a high initial count falling steadily after the start of treatment.

Discussion

Ibadan is in a highly malarious area, and any investigation into the aetiology of anaemia, in any age group, occurring locally must perforce be influenced by this con-

sideration. At the outset of the present investigation we could only guess at the contribution of malaria to the anaemia of infants. We aimed first to eliminate malaria as a variable by giving all our patients a large enough dose of nivaquine to be certain of controlling any latent or overt infection, and decided to use the drug irrespective of the presence or absence of parasitaemia. Besides malaria, the population of Ibadan, because of a deficiency of protein in their diet, suffer from protein malnutrition (Lawson and Lister, 1956).

Woodruff (1955), reporting on work carried out in Ibadan, states: "There is, therefore, evidence that anaemia in some African older children, adult males, and non-pregnant females may be associated with chronic protein malnutrition and liver damage, and this anaemia has the same characteristics as that found in young children and pregnant females." With this in mind, we paid particular attention to the dietary histories of our patients, and in order to avoid confusion we decided to keep them on their accustomed diets until the results of investigation showed the need for a change. The results set out above show that we were able to correct the anaemia in all our patients, without altering the diet, by giving them nivaquine, supplemented where necessary by blood transfusion. Of particular interest is the fact that improvement occurred irrespective of the initial presence or absence of malarial parasitaemia. Trowell (1949, 1956), working in Uganda, found

FIG. 5.—Anaemia of infancy presumed to be malarial. Haemoglobin, reticulocytes, and weight (200-day follow-up.)

that in infancy severe anaemia is usually caused by malaria. He records that following quinine administration combined with a high-protein diet these infants show a reticulocyte response and rapid rise in haemoglobin level.

Iron deficiency is an important cause of anaemia in infancy. Milk-fed infants rely to a great extent on stores laid down in the liver in foetal life, and these in turn depend to some degree on the mother's diet during pregnancy. Premature infants are born with limited iron stores and are prone to hypochromic anaemia. Infections serve to increase iron requirements; infants reared in unhygienic surroundings are thus particularly subject to hypochromic anaemia (Holt and McIntosh, 1953). In Ibadan, maternal diets are generally poor, environmental conditions are unhygienic, and the incidence of prematurity is high (Lawson and Lister, 1956; Woodruff, 1951). It is surprising, therefore, that iron deficiency appeared to play no significant part in the pathogenesis of anaemia in our patients, who, without exception, recovered without being given iron. Clinical evidence and response to antimalarial treatment has led us to conclude that we were dealing with anaemia resulting from infection with *Pl. falciparum*. The efficacy of chloroquine in the treatment of malaria is well established (Trowell, 1956). However, the possibility exists that the drug might have acted in some other manner. Dähne (1943) found that quinine and mepacrine produced a reticulocyte response within three to eight days in normal non-anaemic and non-malarious subjects. He attributed this to a direct action on the bone marrow. In the absence of evidence to the contrary we must recognize the possibility that chloroquine might have acted in a similar manner in our patients.

Bruce-Chwatt (1952), working in Southern Nigeria, found the mean parasite rate in a sample of 138 infants to be: 0 to 3 months, 2.2%; 3 to 6 months, 60.0%; 6 to 9 months, 60-70%; over 9 months, $\pm$ 80%. It will be seen that prior to the third month of life the rate is negligible, but from then onward there is a sharp increase, so that by the age of 12 months 80% of infants have been infected. Reference to Table I will show that this "age of infection" corresponds in our patients with the age group in which anaemia is most common, but, whereas the parasite rate remains high after the first year, the incidence of anaemia declines. This decline in the incidence of anaemia is probably more apparent than real. After the first year the incidence of protein malnutrition rises and patients with anaemia and obvious malnutrition were excluded from the investigation. The explanation may, however, be bound up with immunological responses. During the first three months of life infants appear to be able to resist malarial infection. Thereafter susceptibility increases and anaemia might develop as part of the reaction of an individual with no acquired premunity to malaria. Survival of repeated attacks probably results in increased premunity, with consequent reduction in severity of clinical manifestations.

The anaemia of malaria is generally ascribed to haemolysis, though capillary haemorrhage may play a part (Strong, 1945). The essential features of a haemolytic anaemia are persistent anaemia, persistent reticulocytosis, hyperbilirubinaemia, and excess urobilinogen in the urine and in the faeces (Davidson, 1954). Our patients showed no evidence of haemorrhage. Jaundice was entirely lacking, and only three patients showed serum bilirubin levels slightly in excess of normal values.

In haemolytic anaemia the plasma bilirubin level usually lies between 1 and 3 mg./100 ml., but occasionally it is within normal range, normal levels being maintained by the ability of a healthy liver to excrete far more bilirubin than it is normally called upon to do (Dacie, 1954). Hepatomegaly and high values for the thymol turbidity and zinc sulphate turbidity tests in most of our cases suggest derangement of liver function. It seems unlikely, therefore, that normal serum bilirubin levels were maintained by healthy livers doing more than is usually required. In those patients in whom urine analyses were performed there

was no excess urobilinogen. From our findings it seems improbable that haemolysis was the only factor in the pathogenesis of the anaemia. All our patients showed active erythropoiesis, and it is difficult to reconcile this with the anaemia, seeing that there was no convincing evidence of blood loss by haemorrhage or haemolysis. Woodruff (1951) found a similar discrepancy between the bone-marrow appearances and the peripheral blood in his cases of anaemia of pregnancy in Ibadan; and Altman and Murray (1948, quoted by Woodruff, 1951) made a similar observation in nutritional anaemia of infants.

One is reminded of thrombocytopenic purpura, in which, in spite of a hyperplastic marrow with an increase in megakaryocytes, there is a reduction in the number of platelets in the peripheral blood. Splenectomy often produces dramatic relief in these patients. Wiseman and Doan (1939) described primary splenic neutropenia in which there is agranulocytosis due to excessive phagocytosis of neutrophils in the spleen. The bone marrow in these cases shows a myeloid hyperplasia. Doan (1944, quoted by Nelson, 1945) suggests that "the spleen has an inherent capacity for unusual sequestration and destruction of the formed elements of the blood, and that this function may be stimulated to excessive activity by any condition which causes the spleen to enlarge. In such instances anaemia, leucopenia, and thrombopenia may result because the bone marrow in spite of hypertrophy is unable to compensate." It might be that disturbance of this function is operative in producing the peculiar blood picture which we have described. Results of plasma-volume estimation in our cases suggest that alteration in plasma volume may also be a factor in the pathogenesis of the anaemia.

Summary

Severe anaemia in infancy is often seen at University College Hospital, Ibadan. The results of investigation of 24 cases of severe anaemia in infancy are presented. The typical clinical picture was: a breast-fed baby about 9 months old presenting with fever, cough, and, in 50%, vomiting of one week's duration. Examination showed hepatosplenomegaly, and, in 50%, cardiac signs. The blood showed a normochromic or slightly hypochromic anaemia with anisocytosis, poikilocytosis, and polychromasia. The reticulocyte count was raised and the bone marrow showed a normoblastic hyperplasia. *Pl. falciparum* was found in 13 cases. Serum proteins fell within the normal range for adult Nigerians, and liver-function flocculation tests gave high values in most. The serum bilirubin was raised in only three cases. After correction of anaemia two cases showed a fall in plasma volume.

Treatment consisted only in giving nivaquine (chloroquine) in large doses irrespective of malarial parasitaemia, supplemented by blood transfusion when necessary. No haematinics were given, and patients were maintained on their accustomed diet. There were two deaths. The rest responded to treatment, untransfused patients showing a rapid rise in haemoglobin to normal. A reticulocyte response was noted.

Malaria is thought to be the cause of the anaemia. Malnutrition and iron deficiency play no significant part in the aetiology. The possibility that nivaquine might exert a specific haematinic influence is considered. The absence of evidence of gross haemolysis or haemorrhage in an anaemic patient showing active erythropoiesis is commented on, and it is suggested that abnormal splenic function ("hypersplenism") and alterations in plasma volume may be factors in the pathogenesis of the anaemia.

We thank Dr. A. B. Tompkins and Professor B. Elmes for permission to undertake this investigation; Dr. M. E. M. MacGregor for advice and encouragement; the house officers, ward sisters, and nursing staff of the children's ward for patient and willing co-operation; Mr. D. Simmonds for illustrations; and Mr. J. Garlick for electrophoretic studies.

PROLONGED ANURIA COMPLICATED BY EPILEPTIFORM FITS

BY

T. F. REDMAN, T.D., M.B., F.R.C.S.Ed., M.R.C.O.G.
Obstetrician and Gynaecologist, Leeds (A) Group

AND

F. M. PARSONS, M.B., Ch.B., B.Sc.
Assistant Director, Metabolic Disturbances in Surgery,
Research Unit, Leeds

The dietary and fluid restrictions imposed on patients with anuria has been fully described (Bull *et al.*, 1949; Merrill, 1955). The occurrence of severe convulsions in the course of treatment is not a generally recognized complication.

The patient whose case is described below had very severe epileptiform fits on her 17th day of anuria, and recovered. The management and aetiology of the fits, as well as the nature of the residual renal lesion and its effect on child-bearing, are discussed.

Case History

A primigravida aged 26 was first seen on March 25, 1955, at the 25th week of pregnancy. Her blood pressure was 130/80 mm. Hg; there was no proteinuria or past history of renal disease. During the 29th week of gestation she was admitted to hospital complaining of abdominal pain, vomiting, absence of foetal movement, and anuria for some hours. She was pale and anxious, and her blood pressure was 140/90. There had been no vaginal bleeding. A small quantity of urine was obtained from the bladder by catheter, and there was no proteinuria.

On examination the uterus was hard and tender, and foetal parts could not be palpated nor the foetal heart heard.

Two pints (1,100 ml.) of blood was given, and three hours later uterine contractions were felt, so the foetus was delivered. Eight hours later a stillborn foetus was expelled, with 5 pints (2,840 ml.) of blood clot and the placenta. A further 2 pints (1,100 ml.) of blood was trans-

fused. No fall in blood pressure had occurred since she was admitted to hospital.

After delivery no further obstetrical complication arose, but complete anuria persisted for the first 11 days, and oliguria for another six (see Table and Chart). The anuria

* 550 ml. in faeces. † 400 ml. by enema. ‡ 600 ml. by enema.

was treated on conventional lines at first, with 400 g. of glucose, 100 g. of peanut oil, emulsified to 1 litre of water (Bull *et al.*, 1949). As the anuria persisted the quantity of fluid was reduced to 800 ml. a day, given by mouth as 50% glucose with adequate vitamins. Excessive vomiting occurred on the eighth day, and the fluid was then given by intragastric drip: further attacks of vomiting necessitated changing to 40% glucose, given by caval drip (de Keyser *et al.*, 1949; Bull, 1952; Russell *et al.*, 1954). The electrolyte balance of the patient was followed at frequent intervals, and on the 12th day the serum potassium had risen to 7.6 mEq/l. This was reduced to 4.2 mEq/l. by giving 100 g. of "zeo-carb. 225/Na," suspended in 1 litre of water, administered in five divided doses over two days. The anaemia was twice treated by transfusion of concentrated red blood cells, 2 pints (1,100 ml.) on the sixth day and 1 pint (550 ml.) on the eleventh day.

Epileptiform Fits.—On the 17th day, just as renal function was returning, a series of epileptiform fits occurred, and at the first fit a blood pressure of 220/90 was recorded (a blood pressure of 170/100 had been recorded earlier in the day, a slight rise over the 160/80 of the day before) (see Chart). These fits were not controlled by the prompt administration of 4½ gr. (0.3 g.) of phenobarbitone sodium intramuscularly, nor by 3 g. of NaCl intravenously. The fits started to come at ever-increasing frequency and violence, 10 occurring in about two and a half hours. Thio-pentone sodium, 0.5 g. intravenously, brought immediate respite, and a further 0.25 g. was given when muscular twitching became apparent 15 minutes later. Bromethol ("avertin"), 6 ml. in 8 oz. (230 ml.) of water, was given, and this was followed by a fall in the blood pressure to 140/90. A further 4 ml. of bromethol was given three hours later, when the blood pressure had risen to 195/110. The blood pressure then fell to 165/90, and did not rise again, nor did fits recur. Sodium amylobarbitone, 3 gr. (0.2 g.), was given intravenously for the next six nights, which kept her in a very drowsy state. She was discharged from hospital on the 43rd day after the onset of the concealed accidental haemorrhage.

Fluid and Electrolyte Balance During Recovery Period.—The urine output returned in ever-increasing quantities following the occurrence of the epileptiform fits. During the period of semi-coma the fluid balance had to be maintained with intravenous therapy, and this was reinforced by the addition of sodium, potassium, chloride and bicarbonate. On the 23rd day, when the patient had regained consciousness, she was still nauseated, and the fluid requirement had to be maintained intravenously. This nausea

haemorrhage, although there is no reason to suspect pre-existing renal damage on the findings at her first antenatal visit.

Management of the Anuria

No new principles were involved here. The original recipe of glucose, peanut oil, and water (Bull *et al.*, 1949) is no longer advocated (Bull *et al.*, 1955; Parsons and McCracken, 1957). In particular, the peanut oil has been found unnecessary because, in the first place, the average reserves of fat in a patient developing acute anuria are sufficient to tide the individual through the anuric phase (Merrill, 1955), and, secondly, because of the incidence of nausea and the occasional occurrence of fat pneumonia. The amount of glucose to be administered should be pushed to the maximum dose of toleration for the purpose of reducing endogenous protein breakdown. A glucose-water mixture, adequately supplemented by vitamins, can often be taken by mouth without having to resort to an intragastric drip, but in this patient nausea occurred early, and the intragastric drip had to be used after the eighth day. Then, because of incessant vomiting, 40% glucose was delivered into the inferior vena cava by a "polythene" catheter from the 13th day onwards. Intravenous therapy had to be maintained in this patient even after the anuric phase had given place to the recovery phase, as vomiting and nausea prevented adequate oral intake to keep pace with the urinary output.

The quantity of fluid required during the anuric phase could not be ascertained with certainty in this patient, as no weighing scales were available. The total fluid balance for the first 16 days' treatment is given in the Table: input exceeded output by 8.7 litres, an average of 550 ml. per 24 hours, which probably is the amount of fluid required to satisfy the insensible loss when the water of oxidation and the water released in the cells when protein is

mobilized are taken into consideration. These calculations would suggest that perhaps no overhydration had taken place in the course of treatment. It is, however, emphasized that the fluid-balance chart can be notoriously inaccurate in these situations, and the only satisfactory investigation that can be performed to guard against overhydration is to weigh the patient daily (Merrill, 1955).

The degree of metabolic breakdown that was occurring during the period of anuria was not high in this patient, for the average daily rise in the blood urea nitrogen during the period of anuria was only 11.4 mg./100 ml.

The dangerous rise in the serum potassium level that occurred on the 12th day was treated by giving ion-exchange resin zeo carb 225/Na. As this could not be administered orally it was given by slow rectal drip, the resin being suspended in water. It will be seen from the Chart that this dose of resin successfully reduced the serum potassium level from 7.6 to 4.2 mEq/l.

Epileptiform Fits

The aetiology of the fits can only be a matter for conjecture. It seems unreasonable to postulate the occurrence

of eclampsia as long as 17 days after delivery, unless the renal failure had delayed the excretion of a substance responsible for eclamptic fits. These were associated with a marked rise in the blood pressure, and, although the treatment used in this patient caused a marked drop in the blood pressure with the cessation of the fits, it is no explanation simply to attribute the fits to the raised blood pressure, for this only leaves unsolved the aetiology of the sudden hypertension.

It is well known that overhydration with water can cause convulsions of an epileptiform type, but the fluid-balance investigations did not indicate an excessive intake of water, and certainly no clinical evidence of overhydration occurred. These findings were supported by the fact that rapid intravenous injection of 3 g. of sodium chloride failed to control the fits. Indeed, prior to the onset of the fits sodium had already been administered in the form of the ion-exchange resin.

From the evidence available it can only be assumed that the fits were associated in some way with the anuria and progressive uraemia, for after restoration of renal function the fits ceased and did not recur.

The treatment of the convulsions was entirely empirical, and was based on the management of eclampsia. Thiopentone was used as an emergency, followed by a full dose of bromethol. This was effective in controlling the fits initially, and a further small dose of bromethol was given three hours later, when the blood pressure began to rise again. Fortunately no harm came from the use of these drugs despite poor renal function.

Nature of the Residual Renal Lesion

The presence of proteinuria even one year after the episode of anuria suggests that the renal lesion was of some magnitude, and this is supported by the lowered inulin and P.A.H. clearances. The presence of pus cells also requires further explanation. No organisms were found in the urine either during the period of anuria or subsequently. Cystoscopy revealed no abnormality, and a retrograde pyelogram was essentially normal in the follow-up period. Perhaps the pus cells are the result of gross renal damage undergoing repair.

Future Pregnancies

In the chronic phase of Ellis type I nephritis the chances of foetal survival are very poor, and deterioration of the maternal condition is very great when the blood urea level is raised above 40 mg./100 ml. at the beginning of pregnancy (Dodds and Browne, 1940; Hamilton, 1952). In chronic pyelonephritis of comparable severity, on the other hand, the prognosis for the infant would not be so poor, and the maternal risk would lie more in the danger of superadded acute renal infection. In any case, the possibility of a recurrent pre-eclampsia and even accidental haemorrhage has to be considered. It would seem, therefore, that there would be considerable risk to mother and foetus in a further pregnancy. If the husband and wife are still determined to try again we could only keep a close watch, and offer termination of pregnancy immediately signs of deterioration develop.

Summary

A case is described of anuria for 11 days and oliguria for a further six days following severe concealed accidental haemorrhage.

Epileptiform fits occurred on the 17th day of reduced renal output. They were associated with a sudden rise of blood pressure.

The detailed management of the anuria and of the fits is described.

The results of renal investigations one year later are given. They showed persistent proteinuria and pyuria, with considerable impairment of renal function.

The management of anuria, the possible aetiology of the fits, the nature of the residual renal lesion, and the prognosis for future child-bearing are discussed.

CORTICOTROPHIN IN TREATMENT OF HYPERTHYROIDISM

BY

H. J. B. GALBRAITH, M.D., M.R.C.P.

Senior Medical Registrar, St. Thomas's Hospital, London

AND

J. S. RICHARDSON, M.V.O., M.D., F.R.C.P.

Physician, St. Thomas's Hospital, London

Harris and Woods (1956) reported that electrical stimulation of the tuber cinereum of rabbits by remote control rarely produced the expected increase in thyroid activity unless preceded by adrenalectomy. After reviewing other evidence for the possible inhibitory action of the adrenal cortex on thyroid function, they concluded that further investigation of the effects of corticotrophin administration in early and previously untreated cases of Graves's disease would be of interest. This communication records such an investigation, a preliminary report of which was given by Richardson (1957).

Methods

Eight patients with hyperthyroidism were admitted to hospital. The clinical diagnosis was confirmed by observation for at least 10 days, during which time radioiodine studies and protein-bound iodine estimations were made. Basal metabolic rate (B.M.R.) estimations were also carried out on three days towards the end of the observation period. Corticotrophin gel was then given by intramuscular injection for from two to five weeks, the initial dose of 20 units b.d. being halved in some cases after 7 to 11 days. At the end of the period of treatment the laboratory studies of thyroid function were repeated (Table I). The potency of the batch of corticotrophin which was used throughout had previously been demonstrated on a healthy subject. Confirmation of the efficiency of the adrenocortical stimulation was provided by the fluid retention which occurred and by the increases which were detected in the urinary excretions of 17-ketosteroids and 17-ketogenic steroids. Excessive retention of fluid was combated in the thyrotoxic subjects by injections of mersalyl, but such injections were not given when radioiodine or urinary steroid excretion studies were being made. However, in spite of precautions, pulmonary congestion developed at the end of the course of treatment in two patients.

A ninth patient with hyperthyroidism was treated with prednisone, 20 mg. b.d., for 14 days and studied in a similar way.

Results

A significant improvement in the hyperthyroid state was observed in only one patient, a man aged 40 with mild hyperthyroidism, a diffuse goitre, and symptoms of short duration (Case 2). Even though the improvement was only

decreased and more fluid could be given by mouth, but not until the 31st day of her illness was it possible to stop the intravenous supplement, the caval drip having operated for 19 days. Thereafter the patient returned to a full diet, taking all fluid and medication orally. On the 41st day—that is, two days before her discharge—the output of urine was 1,500 ml.

Subsequent Course.—One year after leaving hospital the patient was reinvestigated. Protein was still present in the urine in considerable quantity, as were a few pus cells and an occasional red blood cell. No casts were found. An intravenous pyelogram showed no abnormality other than a slight distortion of the calices of the left kidney. The plasma levels of sodium, potassium, chloride, calcium, phosphorus, and protein, and the carbon dioxide combining power were within normal limits, but the blood urea was 66 mg./100 ml. The haematocrit reading was 47%. The inulin clearance was 49 ml. a minute, and the P.A.H. clearance 224 ml. a minute. It was apparent, therefore, that considerable impairment of renal function existed. The nature of the residual lesion was obscure, particularly as no values were available prior to the onset of the accidental

slight it was apparent clinically and on each of the laboratory assessments of thyroid function.

Reduction in the size of the goitre was thought to have occurred in Case 3 during the first fortnight of treatment, but further reduction was not seen, although corticotrophin was given for another three weeks. The goitres of the other patients did not alter in size nor was any lessening of proptosis noted.

Although in Case 8 the patient, who had a typical thyrotoxic myopathy, showed no improvement in the hyperthyroid state, a definite increase in the power of the affected muscles occurred during treatment. The electromyographic abnormalities, however, persisted unchanged.

The results in the patient treated with prednisone (Case 9) were equally negative.

Discussion

Hill *et al.* (1950) treated six patients suffering from Graves's disease with corticotrophin in doses of 40 to 200 mg. a day for 5 to 23 days. Two showed an improvement amounting almost to complete remission, in two there was some reduction in hyperthyroidism on laboratory tests only, while two showed no improvement in any respect. Engel (1950) reported a single case of hyperthyroid heart disease in which a 10-day course of corticotrophin produced an immediate improvement in the general condition and was followed in three weeks by disappearance of all clinical evidence of thyroid overactivity. Excellent clinical responses to corticotrophin in single patients were also noted by Means and Stanbury (1950) and by Sideman (1951), although the latter's case relapsed two months after the end of treatment.

Szilagyi, McGraw, and Smyth (1952) investigated the effect of corticotrophin on five patients with hyperthyroidism who had proved unmanageable by the usual medical measures. A definite improvement in the laboratory tests accompanied by slight clinical improvement was noted in one case, deterioration occurred in another, and the three remaining patients showed no clear response. Similarly unsatisfactory results were described by Werner (1950), who treated two patients, and by Moseley and Merrill (1950) and Charvat *et al.* (1952), who reported single cases. More recently Wisniewski and Górowski (1957) gave corticotrophin as a preparation for thyroidectomy to five patients who were intolerant of antithyroid drugs. A reduction in hyperthyroidism was seen in four of the cases. Euthyroidism was never achieved, and relapse quickly followed cessation of therapy.

Thus in 10 of 23 patients with hyperthyroidism significant clinical benefit was obtained from the use of corticotrophin therapy, and this does not accord completely with our experience of only one moderately successful result after the treatment of eight patients. The fact that none of the authors of the single case reports have subsequently described larger series implies that the promise of their earlier successes has not been fulfilled. An unexpected feature revealed by the

analysis of the published results of corticotrophin treatment was the reduction in the size of the goitre in eight patients, often without any reduction in the hyperthyroidism. A doubtful effect was observed in only one patient in our series. The apparent improvement in muscle power in our patient with thyrotoxic myopathy is probably a non-specific effect; Maczynski and Sporny (1956) have described a temporary improvement in general strength in a hyperthyroid patient given 90 mg. of corticotrophin over 20 hours.

There have been several descriptions of the use of corticotrophin and adrenocortical steroids in malignant exophthalmos and in thyrotoxic crisis. In the former most writers agree that a reduction in the local oedema occurs without any improvement in proptosis or ophthalmoplegia. In the latter all observers believe that corticotrophin played an important part in ensuring and accelerating recovery, although all admit that, as other forms of therapy were given concurrently, clinical impressions form the only evidence for this beneficial effect.

The assessments of the function of the adrenal cortex in our patients (Table II) confirm the studies of the majority of preceding workers (Levin and Daughaday, 1955). Two of our cases (Nos. 3 and 4) had definitely subnormal levels of urinary excretion of 17-ketosteroids, while all other

‡ Mean of at least two estimations.

patients had levels in the lower ranges of normality. Glucocorticoid activity as demonstrated by the urinary excretion of 17-ketogenic steroids was not significantly abnormal, and the rather low levels found in our cases are not uncommon in patients with normal adrenocortical activity after a short period of bed rest. As Harris and Woods (1956) pointed out, the surprising feature of these findings is that the urinary excretion of adrenal steroids is not increased in hyperthyroidism, a condition in which the patient would appear to be under physical and emotional stress.

It would seem, therefore, that significant improvement in hyperthyroidism is not to be expected after corticotrophin treatment, except possibly in mild and early cases. For these patients other more satisfactory and safer methods of treatment are available. In patients whose preoperative management is difficult or who develop thyrotoxic crises, the addition of corticotrophin to other therapeutic measures is probably worth while.

Summary

There is much evidence for the association of adrenal cortical underactivity with hyperthyroidism.

Nine hyperthyroid patients had subnormal or low levels of urinary excretion of 17-ketosteroids. The excretion of urinary 17-ketogenic steroids was not reduced.

Eight of the patients were treated with corticotrophin in full doses for two to five weeks. Only one patient showed any significant clinical benefit; this was accompanied by an improvement in all laboratory tests of thyroid overactivity. The ninth patient received treatment with prednisone without benefit.

The radioiodine studies and urinary steroid estimations were carried out in the laboratories of Professor F. T. G. Prunty, to whom we are grateful. We also thank Dr. R. V. Brooks and Dr. J. S. Staffurth for their assistance and Dr. W. J. Griffiths for laboratory facilities.

WAX KERATOSIS IN CHILDREN'S EARS

BY

J. I. MUNRO BLACK, M.D., M.S., F.R.C.S.

AND

R. GEOFFREY CHAYTOR, M.B., B.S., D.L.O.

Consultants, Ear, Nose, and Throat, Newcastle upon Tyne

It was some time before penicillin became easily available in forms which could be used by general medical practitioners, but once this happened it was used freely in the treatment of acute otitis media. In 1953 it was stated that nearly all such cases were being treated by general practitioners, only the failures being seen by otologists (Black, 1954). One of the causes of failure was due to a mistaken diagnosis in that the patient—a child—did not have otitis media, but infection and suppuration in a mass of wax deeply impacted in the external auditory canal. It had long been known that wax did occasionally become impacted against the tympanic membrane, where it became covered by sheets of desquamated epithelium, and we had come to call this "wax keratosis." This was thought to be the early stage of the so-called keratosis obturans, a condition well enough known to appear in the textbooks, although there was discussion about its cause and origin and even about its nature.

This wax keratosis seemed to be of interest in itself, in that we did not know how the wax got into the deeper

external auditory canal, nor quite what troubles it could cause when it got there. Another curious feature was a known association with chronic respiratory tract suppuration, that of sinusitis and bronchiectasis. Morrison (1956) stimulated further interest with a paper on keratosis obturans, in which he suggested an explanation for the presence of the wax against the tympanic-membrane and noted some of the facts of the condition.

Altogether, it seemed to justify some attempt at obtaining further facts, and accordingly an analysis of a collection of such cases has been made, and this forms the basis of the present paper.

Incidence and Location of Wax in Children's Ears

It was important at the outset to have some information concerning wax in children's ears, whether normal or otherwise.

The hair follicles and glandular elements in the skin of the external auditory canal are confined essentially to its outer half or so. Collins (1951) supported previous views that the waxy or more solid secretion of the sebaceous glands is softened by the secretion of the ceruminous glands so that it can find a way to the outside. Therefore it would be expected that wax would normally be found in the outer part of the external auditory canal or not at all (Fig. 1).

An investigation was carried out in 1,000 consecutive children seen for the first time in 1957 in three E.N.T. out-patient departments, perhaps not an entirely normal cross-section of the whole. Three different classes were recognized in these children, as follows: (1) no wax present anywhere in the external auditory canals; (2) wax present in the area which normally produces it; and (3) wax impacted in the deep part of the external auditory canals—that is, wax keratosis.

	No. of Cases	%	No. of Cases	%
1	828	82.8	489	88.4
2	146	14.6	45	8.1
3	26	2.6	19	3.5
Total	1,000	100.0	553	100

A further series of over 500 children were seen in two more E.N.T. out-patient departments. The results in the two series are shown in Table I. It will be seen that 2.6% of the first series had wax firmly impacted against the tympanic membrane. When the wax was removed under general anaesthesia from these 26 children, 14 were found to have a well-formed wax keratosis, and in the remaining 12 the wax had formed a complete cast of the canal, but no epithelial envelope was present as yet. It is probable that these 26 cases represent degrees of the same process, which has been termed wax keratosis. In the second series 3.5% showed the presence of a wax keratosis.

It will be seen that these two series bear a striking similarity, and confirm the incidence of wax keratosis in about 3% of all children attending an E.N.T. out-patient department for a variety of reasons.

Definition and Description of Wax Keratosis

A wax keratosis has been described above as being a mass of wax impacted against the tympanic membrane in the deep part of the external auditory canal. It loses its natural

FIG. 2.—Wax keratosis in deep part of external auditory canal, with thickening and desquamation of epithelium.

brownish-yellow colour to become black and hard, and desquamated squamous epithelium forms a white envelope around it. The condition is usually present in both ears, and it can easily be missed unless a careful examination is made, as the outer half of the external auditory canal is normally free from wax, and the external surface of the wax keratosis tends to be concave (Fig. 2), so as to simulate the appearance of the tympanic membrane. Moreover, we have gained the impression that in cases of wax keratosis the outer half of the external auditory canal is narrow, making examination of the deeper part difficult.

Natural History of Wax Keratosis

Undiagnosed wax keratosis may lie dormant for a long period without giving rise to any symptoms apart from slight deafness, although even this may not be apparent. Audiometer examination suggests that only about 20 decibels of deafness occurs. During this period the surrounding envelope merely becomes thickened by further desquamation of the epithelium.

This process may progress to a stage where the wax keratosis becomes so firm as to erode by pressure alone, first the epithelium of the deep external auditory canal, and then the bony canal itself, giving rise to a true keratosis obturans. A period of many years may elapse before its ultimate discovery, possibly in an adult patient.

The wax keratosis may become infected. This condition can be cured by softening the mass, which is then extruded from the canal during suppuration, leaving a normal tympanic membrane.

Again, granulations may form so as to obstruct the external auditory canal and hide the infected wax keratosis from view. If allowed to go untreated a ring of granulation tissue may form at the junction of the external surface of the wax keratosis and the outer part of the auditory canal. A type of false membrane then develops.

Recurring or chronic suppuration may persist for a long time and cause mistakes both in diagnosis and in treatment. The real condition may become evident only after surgical removal of aural polypi, when it is realized that the trouble is all external to the tympanic membrane. Usually a large polypus, when it occurs, arises from the annulus, and removal leaves a normal tympanic membrane. All trace of wax and keratosis may have disappeared. A great help in the diagnosis is the presence in the other ear of a clean wax keratosis.

Analysis of Cases

The 90 cases available for study included those found during the survey already discussed, along with others previously on record as known cases of wax keratosis. An attempt has been made to analyse these cases, especially with a view to demonstrating conditions which may occur in association with them. These conditions justify an examination of the ears so as to allow early treatment of wax keratosis if it is found.

1. Presenting Symptoms

The reason for the attendance of the child at an E.N.T. out-patient clinic in those cases where a wax keratosis was demonstrated is shown in Table II.

TABLE II

Cardinal Complaint	No. of Cases	%
Deafness	20	22.2
Otorrhoea	17	19.0
Earache	4	4.5
Nasal catarrh	36	40.0
Recurrent tonsillitis	13	14.3
Total	90	100

It is significant that more than half these children were referred without any aural symptoms at all, usually with a history of recurrent sore throat or of a chronic nasal discharge. In these cases the wax keratosis was found on routine examination of the ears. In only two cases in which deafness was the reason for the child's attendance was there a request from the referring general practitioner for removal of impacted wax, for which treatment by softening and syringing had failed. In most of these deaf children post-nasal adenoidal obstruction or previous attacks of otitis media were thought to be the cause of the impaired hearing. When otorrhoea was present it was usually unilateral, and the history was one of failure to respond either to systemic antibiotics, given on the assumption that the cause was acute middle-ear suppuration, or to local treatment, given in an attempt to dry up a chronic suppurative otitis media.

In all groups the most frequent reason for attendance at an E.N.T. out-patient clinic was a request from the medical practitioner for the possible removal of tonsils and adenoids.

2. Condition When First Seen

Out of the 90 children known to have wax keratosis, both ears were affected in 81 cases, and in the other 9 there was a unilateral wax keratosis without any wax at all in the other ear. When the ears were cleaned out under general anaesthesia 68 of the 81 children were found to have a definite wax keratosis in both ears, whilst in the remaining 13 wax was present in the deep external auditory canal but had not yet become surrounded with desquamated epithelium. In the nine children where only one ear was affected, three gave a history of otorrhoea in the unaffected ear which may have given rise to spontaneous extrusion of a wax keratosis, and one was known to have had treatment to the ear elsewhere. Out of the 21 children presenting with otorrhoea or earache, 16 were found to have an acutely infected wax keratosis in one ear, with the formation of granulation tissue.

Several of the children, seen mainly because of aural symptoms alone, and before the relationship with respiratory infection was fully realized, did not have full investigations of their chest and sinuses. These investigations were carried out in 73 children, and the incidence of respiratory suppuration in these children is shown in Table III.

TABLE III

Cardinal Complaint	No. of Cases	Suspected Sinusitis	Obvious Sinusitis	Positive Antral Lavage	Known Chest Lesion	Total with Sinusitis or Chest Lesion
Deafness	15	5	7	11	6	13
Otorrhoea	11	5	4	7	10	11
Earache	4	—	4	4	2	4
Nasal catarrh	36	10	26	29	21	31
Recurrent tonsillitis	7	4	2	5	3	6
Total	73	24	43	56	42	65

Those children who had frank pus in the nose have been listed under "obvious sinusitis." When sinusitis might have been suspected from the history, but the nose was clean, the child was listed under "suspected sinusitis." Many

of these cases showed the presence of pus in the antra when lavage was undertaken. The chest lesions were of all grades, varying from a minor radiological change, usually at the base of the lung, to an advanced bronchiectasis.

It will be noted that 65 (89%) of these children were found to have either a sinus suppuration or a chronic respiratory infection or both.

3. Management

When the implication of the presence of a wax keratosis had been realized a routine procedure was followed in all cases.

Under general anaesthesia both ears were inspected, and the wax present in the deep part of the external auditory canal was removed. This was usually a most difficult procedure owing to general narrowing in the outer part of the canal and the very firm impaction of the wax in the depths beyond. Often this came out as a complete cast of the canal even to the imprint of the handle of the malleus, but occasionally difficulty was found in separating the epithelial envelope from the canal wall, and especially from the tympanic membrane. In these cases only the inner core of wax was removed, leaving the envelope to be extruded later by the normal physiological process of desquamation. Any granulation tissue present was removed by suction at the same time. Proof puncture and antral lavage of both maxillary antra were then performed, revealing in most cases an underlying suppuration requiring further treatment.

Many children had a productive cough which obviously needed treatment, but in those children in whom a chest condition was not so obvious a routine examination, including a chest x-ray examination, was carried out. In this manner about half of the children were found to have an unsuspected chest lesion.

4. Treated Prognosis of the Ears

It is not our intention to discuss the results of treatment of the sinusitis or of the coexistent chest lesion. This treatment is essential, and it has been evident that in children in whom respiratory suppuration remains a wax keratosis can re-form. Probably an important result of this investigation has been to emphasize the likely primary nature of the respiratory infection and the great difficulties experienced in its treatment. Many cases of unsuspected sinusitis and bronchitis have been discovered which would otherwise have continued untreated.

With regard to the ears, they will usually return to normal. When a non-infected wax keratosis has been removed, the tympanic membrane may appear opaque and thickened at first, especially when the outer envelope of the wax keratosis remains attached to it. Gradually this envelope is thrown off and the tympanic membrane becomes perfectly normal in all respects. Any deafness which was present has normally been due to the simple action of the wax keratosis as a foreign body, and the hearing returns to normal when it has been removed.

When the wax keratosis has become infected and granulation tissue has formed, local antiseptic drops may have to be used after the wax keratosis and the granulations have been removed. Once the pressure of the epithelial lining has been relieved there is no of the external auditory canal has been relieved there is no stimulus to the formation of granulation tissue, and in these children as well the ear soon returns to normal.

So long as the associated respiratory suppuration is treated and cured there will be no re-formation of the wax keratosis, and thus we hope that keratosis obturans will be prevented.

Summary

Wax keratosis, if looked for, will be found in about 3% of children attending an E.N.T. department for any reason.

It is almost universally bilateral.

In half the cases there will be no suspicion of any lesion in the ears until they are examined.

Respiratory suppuration (sinusitis, bronchitis, bronchiectasis) will be found, if looked for, in nearly all cases.

The wax keratoses must be removed to prevent the possibility of any future infection, with local suppuration or progression to keratosis obturans. General anaesthesia will be required for this removal and will allow the opportunity for antral lavage.

Chronic suppuration with polypus formation can occur and simulate chronic suppurative otitis media.

Early removal, associated with concurrent and subsequent treatment of any respiratory suppuration present, will result in an ear normal in appearance and in function, with no likelihood of recurrence.

PHYSIOTHERAPY FOR BELL'S PALSY

BY

J. MOSFORTH, M.C.S.P.

Formerly Physiotherapist, Department of Physiotherapy,
General Infirmary at Leeds

AND

D. TAVERNER, M.D., F.R.C.P.

Reader in Medicine, University of Leeds

From the General Infirmary at Leeds

Bell's palsy can be defined as unilateral paralysis of the facial muscles resulting from an intrinsic lesion of the seventh cranial nerve (Cawthorne, 1951). There is general agreement that 70 to 80% of these patients recover completely within one to three months, while the remainder develop various sequelae (Taverner, 1955). There is no agreement about treatment, although many methods have been tried. At present electrical stimulation of the paralysed muscles is widely used, at least until voluntary movement reappears. This practice is supported by many of the standard textbooks (Collier, 1948; Evans, 1951; Nielsen, 1951; Elliott, Hughes, and Turner, 1952; Wilson, 1954; Brain, 1955; Wechsler, 1958), but Walshe (1952) states that galvanism is useless.

There is apparently no record in the literature of a controlled trial of the value of electrotherapy in facial palsy, and the present investigation was undertaken because daily electrotherapy is expensive and time-consuming. It was felt to be justifiable to withhold physiotherapy from the control patients because previous experience has shown that lack of physiotherapy does not necessarily prejudice recovery from peripheral nerve injuries (Henderson and Taverner, 1949).

Design of the Trial

All patients with Bell's palsy of less than 14 days' duration seen in the department of electromyography of the General Infirmary at Leeds from October, 1954, to December, 1956, were included in the trial. The diagnosis of Bell's palsy was made on the basis of the following

three criteria: (1) complete or partial paralysis of the muscles of expression of the whole of one side of the face of sudden onset; (2) absence of any symptom or sign of any other disease of the central nervous system; and (3) absence of any symptom or sign of any disease of the ear or posterior fossa. The patients were examined clinically and electromyographically throughout the course of their disorder. The degree of paralysis was estimated visually as a percentage of the function of the normal side. This method proved reasonably consistent from visit to visit, but was supplemented by photography under standard conditions in many patients.

The electrical examination consisted of concentric needle electrode exploration of the facial muscles without local analgesia. The electrical activity was amplified and recorded with conventional electromyographic equipment. In some patients supplementary studies of neuromuscular excitability were made with a Ritchie-Sneath stimulator.

Denervation of the facial muscles was established by the presence of fibrillation activity in the electromyogram, by abnormalities in the strength-duration curves, and by the subsequent development of abnormalities of the facial musculature during recovery (cf. Taverner, 1955).

All the patients were instructed to massage the face daily, but about half of them, by random allocation from a prepared list, were given daily galvanism by one of us (J. M.). Each patient received infra-red radiation to the affected side of the face at 2 ft. (60 cm.) distance for 10 minutes. The skin was prepared with soap and warm water, and interrupted galvanism was then applied from a Ritchie-Sneath stimulator, using saline electrodes. Each facial muscle in turn was stimulated to 30 minimal contractions with a pulse of 100 msec. duration. This was repeated three times, giving 90 contractions a muscle. In some patients with severe denervation of the facial musculature the muscles tired quickly and the number of contractions was then reduced to not fewer than 30 in three groups of 10. The muscles stimulated were frontalis, corrugator supercilii, orbicularis palpebrarum, levator labii superioris alaeque nasi, levator labii superioris, levator anguli oris, risorius, orbicularis oris, depressor anguli oris, depressor labii inferioris, levator menti. Treatment was given daily until active contractions returned and then thrice weekly until recovery was virtually complete or, in the event of denervation, until the condition seemed stationary. Treatment for patients with denervation lasted from two to six months.

Findings

Of the 86 patients admitted to the trial, three were eventually rejected—two because of failure to reattend, and one because of failure to complete treatment owing to illness. Of the 83 patients studied, 43 received physiotherapy, and 40 were used as controls. The age, sex, and duration of facial palsy did not differ significantly between the two groups (Table I).

TABLE I.—Mean Values for Age, Sex, and Duration of Facial Palsy When First Seen. Range in Parentheses

	Whole Group	Treated	Control
Age	37.5 years (3-79)	39.5 years (3-79)	35.6 years (7-73)
Sex	M.40; F.43	M.22; F.21	M.18; F.22
Duration	5.2 days (1-14)	5.2 days (1-14)	5.2 days (1-14)

It is known that when facial palsy is due to conduction block of the facial nerve no sign of denervation is found and recovery is complete in from one to three months. If denervation of the facial muscles develops, improvement is slower and complete recovery never occurs (Taverner, 1955). The patients in this trial were divided, for purposes of analysis, into those with and those without electromyographic evidence of denervation (Table II). Proportions with conduction block and denervation did not differ significantly between the two groups.

TABLE II.—Proportions with Denervation and Conduction Block in Treated and Control Groups

	Conduction Block	Denervation
Treated	23 (54%)	20 (46%)
Control	27 (68%)	13 (32%)

All the patients with conduction block recovered completely, and the time taken is shown in Table III. The clinical course of patients with conduction block was almost identical in treated and control groups, both in the time taken to initiate movements and in the time to complete recovery.

TABLE III.—Mean Time in Days From Onset of Facial Palsy to First Visible Movement and to Full Recovery in Treated and Control Groups. Range of Observations in Parentheses

	Initial Movement	Full Recovery
Treated	10 (3-21) days	43 (14-90) days
Control	11 (2-21) "	39 (14-134) "

The patients with denervation never recovered completely, and most of them were treated for much longer periods than those without denervation. The times from onset of palsy to first movement were 53 days (range 10-104) in the treated group and 66 days (range 14-90) in the control group. These patients were observed for at least a year or until no further recovery could be detected. The final degree of recovery of voluntary power was assessed visually as a percentage of that of the normal side. An overall estimate of facial movement was made by halving the sum of the percentage estimates of function for the frontalis and orbicularis oris muscles. The last assessments of percentage recovery in the two groups are presented in Table IV. Proportions showing varying degrees of recovery do not differ significantly between the two groups.

TABLE IV.—Estimated Voluntary Power After Maximal Recovery of Denervated Facial Musculature. Figures in Parentheses are Percentages of Respective Totals

	Total	<25%	25-75%	>75%
Treated	20	3 (15%)	11 (55%)	6 (30%)
Control	13	3 (23%)	6 (46%)	4 (31%)

The presence of contracture of the facial muscles was carefully recorded. This appears only after denervation, and its occurrence could not be related to the electrical treatment. Eleven (26%) of the treated group and eight (20%) of the control group developed contracture.

Discussion

The treated and control groups are similar enough to enable useful comparisons to be made. The three defaulters would have added two to the control group and one to the treated group and could scarcely have affected the issue. The results in the two groups are so similar that it is unlikely that electrical treatment can be of importance in the management of facial palsy. The cost to the community and to the patient of daily visits to hospital for electrotherapy does not seem justified on the present evidence. It has been suggested that physiotherapy is valuable for maintaining the morale of the patient. It has been found, in the management of several hundred patients with facial palsy, that if a firm prognosis and careful explanation and reassurance are given then full confidence is maintained.

Summary

A controlled trial of the value of galvanic stimulation in the management of Bell's palsy is reported. Eighty-six successive patients were randomly allocated to treatment and control groups. Eighty-three of them were studied until recovery was complete or for at least one year.

Treatment consisted of infra-red radiation followed by interrupted galvanism to 11 individual facial muscles on the affected side. Treatment was given daily at first and later thrice weekly.

No significant advantage could be demonstrated from the use of galvanic stimulation for Bell's palsy.

LAXATIVE EFFECT OF SORBITOL

BY

RONALD PETERS, M.R.C.S., L.R.C.P., D.A.

Medical Officer to Messrs. Howards of Ilford Ltd.

AND

R. H. LOCK, B.Sc., A.R.I.C.

Messrs. Howards of Ilford Ltd.

As sorbitol is now available commercially and is being used increasingly in food products, its metabolism and other physiological characteristics are of some importance. Apart from its value as a humectant and plastifier useful in confectionery as a diabetetic sugar it is and for increasing the shelf life of the products. Its metabolism has been studied extensively and further work is in progress. In the course of this work it has been observed that, like other sugars of its kind, it exerts a laxative effect, particularly noticeable in large dosage. An attempt to define the threshold dose was made by Ellis and Krantz (1941), who found that by trial on 12 subjects the minimum dose to produce soft or watery stools was about 50 g. a day for the crystalline product and 20-30 g. a day for the 70% syrup (the crystalline compound being much superior in quality to the syrup).

In view of the small number of subjects previously used in these tests the results can hardly be regarded as representative for the general population. We therefore decided to apply tests to a larger number of volunteers to determine the effects at a specified dosage.

Method

Dosage Consideration.—A prerequisite of the tests was that they should not unduly affect the majority of subjects, but should indicate exceptional susceptibility if such should exist. A trial approach was made on three apparently normal subjects, one at a dosage of 50 g., and the other two at 25 g. Only the higher dosage showed spectacular results, and the test level chosen was therefore 25 g. a day.

Of the 101 volunteers taking part, 15 failed to complete the test for reasons unconnected with the effect of sorbitol. Control was obtained by the provision of a glucose solution with an addition of saccharin to match the sweetness of the sorbitol. The volunteers were accepted *en bloc* and no planned distribution of age group, sex, etc., was arranged.

The test consisted in taking 12.5 g. of either sorbitol or glucose after meals twice daily for seven days, half of the panel taking sorbitol and the other half glucose, and then changing over to the other substance for a second week. So far as the subjects were concerned, the solutions were identical in appearance, colour, and taste.

The solutions were: (1) a 50% w/v solution of glucose in water and (2) a 50% w/v solution of sorbitol in water to which was added 0.04% w/v of saccharin (based on the sorbitol content).

Each subject was given a supply of test solution sufficient for one week and invited to complete a questionnaire day by day. The 101 volunteers are accounted for as follows: completed tests both weeks, 84; tests not completed owing to alleged effects of sorbitol, 2; tests not completed for reasons not connected with sorbitol, 8; tests not started for personal reasons, 7.

Results

Analysis of the factors, such as rotation of dosage, method of dosage (as supplied or in a beverage, etc.), age group, occupation, marital status, and some others, not all of which are analysed in the accompanying Table, did not

Table of Results

Occupation	Status	Solution Used	Age Groups				Totals	
			Under 30		Over 30		Sub.	Mot.
			Sub.	Mot.	Sub.	Mot.

Totals	{	Glucose	26	188	58	483	84	671
		Sorbitol	26	187	58	561	84	748

Sub. = Subjects. Mot. = Motions.

reveal any significant effects. In view of this the significant differences between sorbitol and glucose (standard deviation, 4.99 and 2.95 respectively; DF, 83) must be attributed to some other factor not disclosed in the group allocations.

By inspection three results were seen to be outstandingly divergent from the general run. A recalculation of standard deviation of the glucose and sorbitol series after eliminating these cases gave a standard deviation of 2.90 for glucose and 2.95 for sorbitol (DF, 80) indicating that the two series show no significant difference.

A fuller statistical analysis of the factors and interactions was found to be beyond our competence owing to the complications of disproportionate class numbers.

Inspection of the observations on "wind" showed a definite tendency to flatulence due to sorbitol.

Comment

Olmsted (1953) commented on the results of Ellis and Krantz (1941) and suggested that sorbitol may be a physiological laxative in the sense that it is a substrate for the colonic bacterial populations. It has been shown, however, that, in general, sorbitol is a poor nutrient for the more common bacteria, and it seems more likely that its humectant properties are the cause of the laxation observed at higher dosages.

We conclude that sorbitol administered in a split daily dosage of 25 g. does not cause laxation in the general population, but specific reactions may be expected from about 5% of the subjects. In practice it has been noticed that the presence of fats in foodstuffs allows much larger doses to be tolerated without laxative effects. In view of the increasing use of this product in the confectionery trade, it might be well to bear in mind the possibility of a sorbitol sensitivity as a cause of diarrhoea in an otherwise healthy subject.

Summary

The laxative effect of sorbitol was compared with the control glucose at a dosage level of 25 g. a day for 86 subjects; observations included the number of motions, and incidence of wind and of discomfort or pain. Discomfort and marked laxation were experienced by five subjects, two of these failing to complete the test. The remainder showed no significant difference from the glucose control with the exception of a slight tendency to wind after ingesting sorbitol. No known diabetics were allowed to participate in the tests.

Acknowledgment is made to Messrs. Howards of Mford Ltd. for assistance in facilitating these tests.

Medical Memorandum

A.T.S. Cervical Polyradiculitis Treated by Cortisone

Neurological sequelae of serum therapy are well recognized. Miller and Stanton (1954) analysed the hundred adequately documented cases. Of these, 59 had brachial plexitis, 15 had other forms of radiculitis (radicular neuritis, mono-neuritis, shoulder-girdle neuritis), 10 had polyneuritis, 6 had Landry's paralysis and myelitis, and 10 had cerebral and meningeal manifestations. Moynihan (1955) found that one patient developed peripheral neuritis in 7,580 cases given prophylactic A.T.S. (antitetanus serum).

These syndromes are severe complications. "Progress may be slow, and, while improvement in patients with plexus and single-nerve involvement may start in a month, complete recovery may be prolonged up to two years. According to most writers, about 20% of patients never achieve a complete return of function" (MacGibbon, 1955).

As these syndromes are believed to have an allergic basis, an anaphylactic hypersensitivity, and as cortisone has been successful in non-neurological drug-hypersensitivity states (Carey *et al.*, 1950) and in encephalomyelitis following anti-rabies vaccine (Garrison, 1952), it is important to assess the value of steroid therapy in serum neuritis.

Cortisone had no effect on peripheral neuropathy which developed after A.T.S. in a patient (Walsh, 1952), but here the cortisone was not given until the third day of muscular weakness, and then only 50 mg. intramuscularly twice daily for 10 days. However, Shulman *et al.* (1953) produced a complete remission in a case of A.T.S. sciatic neuritis with a single intravenous infusion of corticotrophin; and Shafer (1957), using oral prednisone, 5 mg. six-hourly, relieved the pain in a case of A.T.S. shoulder-girdle neuritis in one day, with return of muscle power to normal in 10 days.

CASE REPORT

A sergeant, aged 36, cut his right hand on March 22, 1957. The wound was sutured but became infected, and on March 29 he was given injections of A.T.S., 1,500 units, in his right arm, and of fortified procaine penicillin, 1 ml. twice daily, in his buttocks, on that and the next two days. On April 4 he noticed that his right arm was itching, swollen, and red. At 10.30 that night an aching pain began in the left side of his neck, and spread gradually down the back, into the calf, and from the left shoulder down the arm to the elbow. These pains became worse when he moved the shoulder or sat up. Although he felt quite well otherwise, these aches were severe enough to make him come for admission to the Royal Herbert Hospital, Woolwich, at 3.30 a.m. on April 5. The only significant features of the history were that he was left-handed, that he had had penicillin injections before with no ill effects, and had been

given tetanus toxoid-antitoxin in 1937 and tetanus toxoid in 1938, 1939, 1942, and 1944.

On examination he was distressed and in obvious pain. His whole body with the exception of his head was covered with a fine erythematous eruption. He was afebrile, the scar on the right hand was soundly healed, and there was no swelling or tenderness at the sites of the injections. There were no other abnormal signs in the central nervous or any other system.

The haemoglobin, total and differential white-cell counts, and, later, x-ray films of the chest and cervical spine were normal. A diagnosis of serum sickness was made, and promethazine hydrochloride, 25 mg. six-hourly, was given.

By the following day (April 6) the rash had disappeared and the only pain was in the left upper limb, which he then noticed had become weak. There was no wasting or fasciculation, but tenderness of the muscles of the left upper arm was present and also profound weakness of the left pectoralis major, infraspinatus, deltoid, biceps, triceps, and brachioradialis, the flexors and extensors of the wrist and fingers, and the small muscles of the hand. The left supinator and biceps jerks were absent and that of the triceps was much reduced. There was impairment of superficial sensation over the radial side of the left lower forearm, the thumb, and index finger in the distribution of C6 dermatome. It seemed clear that the patient had serum neuritis, with a unilateral cervical radiculitis involving the left C5-8 and T1 roots, especially C6. He was given cortisone by mouth, beginning with 75 mg. six-hourly.

By the next morning (April 7) the aches were much less, and his power had improved remarkably both subjectively and objectively, while the sensory impairment was confined to a small area on the radial side of the left wrist and over the first metacarpal bone. The cortisone was decreased to 200 mg. that day, and the next morning he had some recurrence of pain in both shoulders. His power had continued to improve, and he was given 100 mg. of cortisone that day. On April 9 power and sensation were normal and his deep reflexes had all returned, though still reduced. The cortisone was continued at 100 mg. that day and then gradually tailed off over the next fortnight, so that he received a total of 1,175 mg. over 18 days.

On discharge from hospital on April 26 his only complaint was of slight ache over the left deltoid. One month later he was well and symptom-free; the only abnormal sign was a slightly decreased left biceps reflex.

COMMENT

In view of the unfavourable prognosis of serum neuritis it seems reasonable to attribute the rapid recovery in this patient and in those of Shulman *et al.* and Shafer to the use of cortisone, corticotrophin, and prednisone respectively. Such dramatic response lends support to the suggested "allergic" basis in this condition, and would suggest that early and sufficient steroid therapy is the most hopeful treatment available for serum neuritis. In the identical clinical picture of localized neuritis of the shoulder girdle or neuralgic amyotrophy (Spillane, 1943; Parsonage and Turner, 1948; Turner and Parsonage, 1957), when the miscellaneous precipitating factors include trauma and infection, it would seem worth while to attempt steroid therapy if it could be given as early as possible in the course of the disease.

Reviews

GENERAL PSYCHOPATHOLOGY

An Introduction to Psychopathology. By D. Russell Davis. (Pp. 388+vi. 30s.) London: Oxford University Press. 1957.

We have long lacked in Great Britain any book on general psychopathology which can be recommended with confidence to the student. In this way we are badly handicapped in comparison with Germany, for instance, where in every textbook of psychiatry a substantial part of the whole volume is given to this part of teaching. What we have had instead is a number of works, many of them of great excellence, on psychopathology in the limited Freudian sense. Dr. Russell Davis has now supplied the deficiency with a book which covers the whole ground and is so lucid and intelligent that it is a pleasure to read. The author's basic tenet is that the most promising line of advance in psychiatry at the present time lies in the application of the findings of experimental psychology. His book is essentially the discussion of mental illness in the context of psychological theories. This is done with great ability, and the evidence has been collected and presented in a critical and stimulating way. Nevertheless the result is a work which is, as the author himself admits, somewhat one-sided in nature. The lack of appreciation felt for observations and theories along physical, medical, and genetical lines constantly involves him in difficulties. In presenting the hypothesis of a purely environmental and psychological causation for some condition he has to say that "there is little conclusive evidence with which to support it" or that it "would be possible to deny any weight to the arguments from which the theory has been built up." Though it is always made clear to the reader when the author's partialities are taking him beyond the evidence, one cannot but regret that a more judicial attitude was not found possible.

Despite these criticisms, this is an excellent and important book. It will not escape the thoughtful reader that in the present state of knowledge the psychological theories cannot bear the whole of the weight that is placed upon them. Yet the author has collected a mass of data, especially from the fields of experimental psychology and sociology, which are not easily available to psychiatrists, and he has pointed out lines of approach which may very well prove fruitful. Teachers and students are alike in his debt.

ELIOT SLATER.

CHEMOTHERAPY

The Strategy of Chemotherapy. Eighth Symposium of the Society for General Microbiology, held at the Royal Institution, London, April, 1958. Edited by S. T. Cowan and E. Rowatt. (Pp. 360+ix. 35s.) London: Cambridge University Press. 1958.

The title of this symposium evokes ideas of therapeutic policy. When is it better to attack promptly, and when to delay a declaration of war until an ally, the normal body defences, has mobilized and gone into action? Should the entire force be engaged in the hope of a single decisive action, or should there be a strong reserve or a deliberate policy of attrition? When is a combination of different arms to be preferred to deploying a single one? If there are two enemies, should they be engaged successively or together? At what point does the devastation caused by a campaign outweigh the fruits of victory? How far is it wise to go on provoking a fresh enemy to declare a war of superinfection? Perhaps these are matters of tactics, but the reader who looks for them here will be disappointed. Most of the 14 British and five American contributors are concerned either with the design of weapons used in this sort of war or with the kind of injury they inflict. There are those which destroy the bacterial cell wall or interfere with its construction, those which interfere with the metabolism of either carbohydrate or protein, and some which

divert a metabolic process so that an abnormal and toxic product results ("lethal synthesis"). There are others, it may be added, and not the least useful therapeutically, the mode of action of which cannot be so confidently defined. In the search for new weapons the random method has so far produced everything of any therapeutic importance which we possess; in future the rational method, on some such lines as the contribution here on the designing of antimetabolites, may yield more fruitful results. Several concluding contributions include one devoted very appropriately to the mechanisms of synergy, and others which are general accounts, with some discussion of the causes of failure, of the possibilities of chemotherapy in infections by bacteria, protozoa, and fungi. The authors of the last-named could have been less pessimistic about treating systemic mycoses if they had included some reference to amphotericin.

The Society for General Microbiology is again to be congratulated on publishing in a very handsome volume a series of contributions by experts in the rapidly expanding field shared by the bacteriologist and the biochemist. The progress which is being made in these fundamental studies is on a wide front and equally impressive in its depth. It is interesting that several contributors quote sayings of Ehrlich as directly applicable to the problems of the present day.

L. P. GARROD.

LESSONS IN MEDICAL EDUCATION

Adventures in Medical Education: A Personal Narrative of the Great Advance of American Medicine. By G. Canby Robinson, M.D., LL.D., Sc.D. (Pp. 338+xii; illustrated. 40s.) Cambridge, Massachusetts: Harvard University Press (for the Commonwealth Fund). London: Oxford University Press. 1957.

This is the autobiography of an octogenarian physician who looks back on his full and well-spent life and draws some lessons from his experience. Its main interest lies in the vivid insight it gives into the transition stage of American medical education at the beginning of the present century. Both in Great Britain and in the United States medical education during the past 200 years has gone through three stages—apprenticeship, private medical schools, and university medical schools. Dr. Canby Robinson took a considerable part in helping to make smoother the introduction of full-time academic professors and to lessen the disturbance in the change-over from private to university control in several big centres. Born in Baltimore, and trained at the Johns Hopkins Medical School, where he was inspired by Osler, Welch, Halsted, and Howard Kelly, he served as intern at the famous Philadelphia Hospital and had the good fortune to be appointed the first senior resident physician at the newly opened Hospital of the Rockefeller Institute. From there he went to take the position of associate professor of medicine in the Washington University Medical School at St. Louis, where he played an important part while full-time professors were being installed. Moving on to Nashville in 1920, he took a large share in planning, building, and staffing the new Vanderbilt University Medical School, and from there he went as director of the newly formed association between the New York Hospital and the Cornell Medical College. These experiences entitle Dr. Robinson's opinions to respect, and he is in no doubt as to the value of full-time professorships in medical education, though he appreciates the ever-present difficulty about permitting some private practice.

The generosity of private donors in America at that time was astonishing. From 1910 to 1935 over 500,000,000 dollars were thus contributed to medical education. Yet costs of running the medical schools continue to rise and cause financial worry. Dr. Robinson's later years were spent in research in social medicine, and he has some useful words to say on that branch of the profession. He pays a just tribute to the late Professor Ryle. The last chapter in the book is a useful essay (really a sermon) on medical progress during the last 50 years. He sums up briefly: "Medical education should cultivate the love of

God, the love of man, and the love of truth because these form the foundation on which medicine should be firmly based." Though serious-minded, the author has a sense of humour and relates this story. Chancellor Kirkland was the moving spirit at Vanderbilt University. He was a keen gardener, and one day when, dressed in very old garments, he was working in his garden, a lady who was passing admired the flowers and said to him, "Do you work for Chancellor Kirkland?" Concealing his identity, the Chancellor replied, "No, ma'am; I work for Mrs. Kirkland." One can see why he was made Chancellor.

ZACHARY COPE.

DIATHERMY

The Principles and Practice of Diathermy. By Bryan O. Scott, M.R.C.S., L.R.C.P., D.Phys.Med. (Pp. 193 + vii; illustrated. 25s.) London: William Heinemann (Medical Books) Ltd. 1957.

This is a useful book. The author briefly traces the history of the discovery of high-frequency currents and their application to medicine, and then covers succinctly the basic physics necessary for the complete understanding of the subject. Here he succeeds in getting a lot into a small space, and illustrates his points with simple analogies. Chapters on short-wave generators and high-frequency fields follow. The techniques of the introduction of energy into the body are described in full. The effects of high-frequency currents are discussed; these are the heating of the tissues, and the author wisely discounts any specific effects of short-wave diathermy apart from heat. Indications and contraindications to short-wave diathermy are discussed. A brief chapter describes the dangers of diathermy and their prevention. Surgery is not neglected, and the fundamentals of electro-desiccation, electrocoagulation, and electrosection are given. Finally the techniques of regional application are well and usefully described. Both a glossary and index are provided. The author is generous in his acknowledgments, but it is obvious that he has done much work himself in this field. Both physiotherapists and doctors who are taking up physical medicine will welcome this book.

WILLIAM TEGNER.

STAMMERING

Stuttering: A Psychodynamic Approach to its Understanding and Treatment. By Dominick A. Barbara, M.D., F.A.P.A. (Pp. 255. 25s.) London: Hutchinson Medical Publications. 1958.

This is the third book on this subject that has appeared recently, each one written by a therapist who had himself stammered earlier in life. Dr. Barbara's approach, however, differs from that of his two predecessors in that it was only after several years of training at the American Institute of Psychoanalysis that he was ready to combine his personal experience as a stutterer with Karen Horney's theory of psychoneurosis in the treatment of stuttering. It is not surprising, therefore, that the author's views as to the aetiology of stammering or stuttering are concerned mainly with psychological factors, and that he regards the disorder as primarily due to the anxiety of the stutterer in attempting to adjust himself to other individuals. Treatment, therefore, should not merely consist in vocal exercises and suggestions; it must be directed to the entire personality of the patient. With regard to the designations "stammering" and "stuttering," it is generally accepted in Great Britain that the two terms are synonymous, the former being used almost exclusively in this country and the Dominions, while "stuttering" is preferred in the U.S.A. Dr. Barbara, however, quotes J. S. Greene as stating: "According to the derivations, 'stuttering' stands for laboured, difficult, and hesitant speech with resulting defective conversation, while 'stammering' refers to defects of articulation and should not be confused with 'stuttering'; technically, stuttering is known as dysphemia, while stammering is known as dyslalia." This view, however, has never been held in Great Britain, where the term "dyslalia" is applied to a speech

disorder entirely different from stammering or stuttering, while "dysphemia" is sometimes used as an alternative for the latter condition.

The book is evidently intended not only for the professions of medicine and speech therapy but also as a help to families of child stutterers as well as adult sufferers. The incidence of the disorder and the various views concerning aetiology are discussed; also the symptomatology, illustrated by several case histories, is well presented. A chapter is provided on the "Demosthenes complex," as it is termed by the author, and which is defined as a process of self-glorification in stuttering based on an accentuation of anxiety and fears in the speaking situation; thus, in association with the stutterer's particular make-up, there is created an idealized image of his own particular needs. In the treatment of "primary" stuttering (5-10 years of age) the approach is mainly one of treating the parents and through them endeavouring to remove unfavourable influences, to give support, and yet help the child to lessen the degree of his inner turmoil and conflicts and so prevent the perpetuation of the disorder into the secondary stage. In "secondary" stuttering (11-19 years) treatment consists in a more direct approach, the aim being reorganization of the patient's personality, which admittedly is a tedious and difficult undertaking.

The exact causation of stammering or stuttering remains an unsolved problem. It is practically certain that no single factor but several in combination are concerned in the aetiology of the disorder. Psychogenic symptoms are only too frequent, but most of these may well be secondary to the primary stammer. Few cases, in my experience, are relieved of their stammer by psychotherapeutic, or even psycho-analytical, methods alone. Nevertheless, Dr. Barbara's work is well worthy of study by those interested in the problem of stammering (or stuttering), as he writes from a basis of considerable experience and a wide knowledge of the literature of the subject.

C. WORSTER-DROUGHT.

ELECTROCARDIOGRAPHY AND VECTOR-CARDIOGRAPHY

Fundamentals of Electrocardiography and Vectorcardiography. By Lawrence E. Lamb, M.D. (Pp. 142 + xiii; illustrated. 72s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1957.

The subtitle of this book, "Three-dimensional Quantitative Spatial Vectorcardiography," certainly sounds rather formidable. But this is not really the case. If anyone wants to have a knowledge of electrocardiography that is not merely descriptive, this is the sort of book to read. The subject will then be approached from the angle of interpretation, which should result in full understanding. There is nothing really abstruse in vectorcardiography, and to translate the ordinary electrocardiogram into these curves is not really difficult—a further step leading to consideration in three dimensions instead of two is not insuperable. There are certain mathematical aspects, but it is not really essential to master these. This book sets forth the subject very clearly. There are many excellent diagrams. At the end there are chapters on the arrhythmias and also on drugs and cardiac metabolism. Throughout there is laudable economy of expression, but this does not obscure the thought; rather the reverse—it adds to the clearness. This book can be fully recommended for study; it is one of the best I have met with so far.

TERENCE EAST.

The fourth edition of Professor E. J. Conway's manual on *Microdiffusion Analysis and Volumetric Error* (Crosby Lockwood, 1957; 465 pages, 42s.) incorporates descriptions of several recent advances in technique, including the use of the blood ammonium method in the study of liver disease and the method of Weil-Malherbe and Green for total nitrogen determination in brain slices, and an account of some new developments in apparatus.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 13 1958

SURGERY FOR DEAFNESS

For the perception of sound an intact end-organ and central connexions are necessary, and also an unobstructed conduction pathway. In addition, the sound waves must be received at the oval and round windows with a suitable phase difference. This is normally provided by the chain of ossicles in the middle ear transferring sound vibrations from the drum membrane to the foot-plate of the stapes and thence to the oval window, while at the same time these vibrations are conducted directly through the air space of the middle ear to the round window. Movements of the oval window are transferred to the incompressible fluid occupying the inner ear and are reflected in movements of the round window in the opposite phase. Motion thus imparted to the fluid of the inner ear stimulates the organ of Corti, the end-organ of perception. But these movements depend on there being a sufficient phase difference at the oval and round windows.

Transference of sound waves through the middle ear is affected by, firstly, lesions of the drum membrane and of the middle ear impairing the integrity of the ossicular chain or restricting its mobility by adhesions; secondly, scar tissue in the round window niche or at the foot-plate of the stapes; thirdly, fixation of the stapes foot-plate by bony ankylosis. Lesions in the first group are usually the result of suppuration, and the possible methods of treatment have been discussed.¹ Lesions in the second group may result from inflammation, or may be due to the organization of residual mesenchymal deposits, the so-called chronic adhesive process. The treatment will be considered with that of the third group.

The most common cause of fixation of the stapes foot-plate is otosclerosis, a condition in which new bone forms in the inner ear capsule, usually in the neighbourhood of the oval window, and perhaps because of an attempt at healing a persisting embryonic defect. This new bone gradually invades

the margins of the oval window and restricts the free movement of the stapes. In time the annular ligament attaching the foot-plate to the bony wall of the window becomes infiltrated with bone, which ultimately spreads into the foot-plate itself. These changes cause increasing deafness. The process is sometimes rapid, almost fulminating, but more often it takes years; it may be arrested at any stage and never produce complete bony ankylosis. This pathological process, although not the reason for it, has been well known for many years, and the theoretical possibilities of treatment have also been formulated and to some extent practised for years, but it is only within the past two decades that surgical treatment has become safe and the results reasonably predictable.

Six years ago Samuel Rosen, of New York, published his first series of cases treated by mobilization of the stapes foot-plate, and he has recently summarized for a British audience the progress during the intervening period.^{2,3} The method is essentially simple, and it seems almost absurd that success has taken so long in achievement. The use of magnification, scrupulous technique, and antibiotics all play their part, especially the first two. After local analgesia the drum membrane is reflected from its posterior attachment and the incudo-stapedial joint is exposed. It is often necessary to remove some bone from the postero-superior portion of the tympanic ring to obtain a good exposure of this joint and of the stapes foot-plate and round window which are the next essential anatomical landmarks. All this area is carefully inspected under high magnification. In cases of chronic adhesive deafness, the constricting adhesions are divided or dissected away. In otosclerosis, by Rosen's original method, an instrument is placed on the neck of the stapes and with light and controlled pressure the bone is rocked and the foot-plate is wholly or partially fractured out of its bony confinement. This procedure is unsuccessful in a number of cases because the ankylosis is too dense and the slender crura of the stapes give way before the ankylosing bone. When this appears likely the foot-plate is directly approached and attempts made to pry it loose. Even this may fail, and Rosen then resorts to making an opening in the foot-plate itself.⁴ The drum membrane is replaced at the end of the operation. By these simple but delicate manoeuvres hearing can be improved, and sometimes restored nearly to normal, in many cases of otosclerosis. Provided the organ of perception is functioning normally or reasonably well, good results can be expected in over 50% of cases, and this proportion increases as the operator's skill improves.⁵ There

⁷ Lempert, J., *Arch. Otolaryng.* (Chicago), 1938, 28, 42.

are certain possible operative accidents, but they should be few and of little account. There are almost no contraindications, once the case has been selected, and the patient is only off work, or out of circulation, for a few days.

It is now exactly twenty years since Julius Lempert, of New York, published his first series of cases treated by fenestration.⁶ The idea of making a bypass opening somewhere in the capsule of the inner ear to act in concert with the round window is very old, and many attempts at it were made in past years. However, Lempert's technique was the first successful one. It too requires scrupulous care. A new opening (fenestra) is made in the external semicircular canal. This opening is covered with a flap of skin from the external meatus continuous with the drum membrane, and lies exposed to the outside world in a cavity similar to the cavity of a modified radical mastoidectomy. The drum membrane adheres to the inner wall of the middle ear above the round window, which is thus enclosed in an air-containing space continuous with the Eustachian tube. This arrangement ensures that sound waves arrive at the fenestra and the round window in a different phase, so that they can be propagated through the labyrinthine and cochlear fluids. These conditions are essential for a successful result. In the performance of the operation the incus and the head of the malleus are sacrificed, resulting in an inevitable loss of hearing, between twenty to twenty-five decibels by calculation and confirmed by observation. Thus the hearing can never be restored to normal by a fenestration, however successful, whereas stapedolysis can in theory result in normal hearing, and in practice some cases come very close to it. Nevertheless, the perfecting of the technique of fenestration during the twenty years of its enthusiastic performance all over the world has led to considerable certainty in the result to be expected in any given case, and to a high percentage of successful cases.

Fortunately, Rosen's and Lempert's procedures are complementary. If the direct attack on the stapes is unsuccessful, the indirect one, a fenestration, is neither invalidated nor prejudiced, and the operation can be performed as soon as the meatal wall is soundly healed. It is now usual to advise stapes mobilization as a first procedure, and fenestration if it fails. Surgery therefore has much to offer in deafness due to otosclerosis, and increasing experience is showing that some cases of chronic adhesive deafness can also be improved. These advances, together with similar advances in the surgical treatment of cases of suppuration, and the rapid improvement in construction of hearing-aids, are opening many new doors to the deaf patient.

HYPNO-ANAESTHESIA

Five thousand years ago man knew a great deal about influencing the psyche for the benefit of the sick or stricken soma. To our Western culture at least this knowledge has been largely lost. Perhaps the current waxing of interest in hypnosis marks the onset of a systematic effort to regain it.

Over the ages every type of operative procedure, major and minor, has been carried out under hypno-anaesthesia alone. In the last century Elliotson¹ and Esdaile² each wrote accounts of such work. Induction of hypnosis and the termination of the state are as smooth as falling into and awakening from natural sleep. While under hypnosis a patient may be made insensitive to pain from any defined area and also be made incapable of any given movement or of altering any desired posture.³ Indeed, he can be enabled to maintain any desired posture indefinitely and without conscious effort, strain, or fatigue. Post-hypnotic suggestion will permit a suggestion given to the hypnotized patient to become effective immediately and remain effective after the hypnotic state has been terminated, or to become effective at some chosen moment in the future. During operation the patient may be kept conscious and fully co-operative, or placed in a state akin to normal sleep in which he is oblivious to his surroundings. All these phenomena can be made to cease in a moment and normal consciousness to be regained by appropriate counter-suggestions from the therapist. During and after operation there will be no complications directly attributable to the anaesthetic.

From this it would seem that hypnosis is the ideal anaesthetic for most kinds of surgery, and the question which at once arises is why it is not more widely used. The answer is that, though the mechanical aspects of the techniques for inducing hypnosis are easy to learn, successful induction largely depends on the interaction of factors in the personality of the patient which are but little understood with factors within the hypnotist which are not understood at all; and few therapists could guarantee to produce surgical hypno-anaesthesia in one in a hundred unselected surgical cases. Further, even the most favourable case might require three or four hours' work on different occasions before it was felt justifiable to operate. There is no quick and certain test to indicate the promising subject.

⁴ Kroger, W. S., and Deloe, S. T., *J. Amer. med. Ass.*, 1957, 163, 442.
⁵ Amer. J. Obstet. Gynec., 1946, 51, 544.
⁶ Abramson, M., and Heron, W. T., *ibid.*, 1950, 59, 1069.
⁷ Kelsey, D., and Barron, J. N., *Brit. med. J.*, 1958, 1, 756.

Perhaps the chief indication for hypno-anaesthesia is in obstetrics.⁴⁻⁶ Expectant mothers are apt to be good hypnotic subjects, and weekly training throughout pregnancy at the antenatal clinic would enable many labours to be completed without additional anaesthetics. This would mean that the mother would be fully conscious as she gave birth to her baby, to their great mutual benefit. It would also ensure that birth was as easy as possible for the baby, and in particular it would minimize the risk of the baby losing consciousness during the process of birth. Some workers believe that this is of importance for the future psychological development of the child. D. Kelsey and J. N. Barron⁷ recently used hypnotically induced catatonia as the sole means of keeping a patient in a hand-to-foot posture for 28 days for purposes of plastic surgery. This application might possibly be extended to some orthopaedic work.

The same authors suggest that hypnosis would be advantageous for patients with severe burns who require a daily anaesthetic for their dressings and for whom every meal missed adds to the difficulty of maintaining the level of plasma proteins. Dentists³ have found hypno-anaesthesia of value in the treatment of both adults and children. Once analgesia has thus been successfully induced in the mouth, the patient can have it reinduced, or be trained to re-induce it himself, at will for the rest of his life. Some success has also been achieved in keeping the acute pain of earache, toothache, and some injuries at bay until adequate treatment could be instituted, and also in controlling the pain of inoperable malignant disease.

Though hypnosis is out of the question as a routine general anaesthetic, its advantages might be brought to many more surgical patients than at present if special hypnosis clinics were set up, experimentally at first, in the larger hospitals. Patients awaiting a non-urgent operation would be invited to attend the clinic on several occasions prior to admission. The clinic would work largely with groups, and the main aim would be to allay pre-operative anxiety and, by the use of post-hypnotic suggestion, forestall post-operative symptoms and complications. If a patient suffered no pain from his wound, for example, he would breathe and cough freely, thereby eliminating what is usually held to be the greatest single cause of post-operative chest disease. Sleep and appetite could be improved and appropriate individual suggestions could greatly assist the work of physiotherapists. In brief, convalescence and rehabilitation could be made smoother and speedier for many of the patients attending the clinic.

EARLY CARCINOMA OF STOMACH

The occurrence of early carcinomatous lesions in the stomach has aroused considerable interest during the last few years, and a case recently described by J. J. Bocian and A. E. Geschke¹ is regarded as a true example of carcinoma in situ. These authors are at pains to distinguish carcinoma in situ of non-polypoid form from superficial spreading carcinoma of the stomach. Both types of growth may replace the normal glandular tissue of the mucous membrane over a considerable area.

Carcinoma in situ occurs in the stomach in two forms, polypoid and non-polypoid. Polyps showing malignant appearances in some cells are occasionally found in the stomach, analogous with similar polyps occurring in the rectum, and in both sites they are apt to become malignant at a later date. From the edges of such a polyp, non-polypoid carcinoma in situ may spread along the gastric mucosa. In the non-polypoid form, which tends to occur in the pre-pyloric region, the abnormal cells of malignant appearance are confined within the basement membranes of the glands. These cells are atypical in form and arrangement; their nuclei are hyperchromatic and mitoses are frequent. A bizarre glandular pattern is produced which does not necessarily involve the deeper portions of the glands. The lesion may not be continuous, and necrosis and ulceration of its surface may be found.

T. B. Mallory² has reported seven cases of carcinoma in situ of the stomach, three of polypoid and four of non-polypoid form. In this small group there was no evidence of recurrence or of metastases in the intervals from one to seven years after resection of the stomach.

The superficial spreading carcinoma of the stomach, especially prone to occur in the pyloric antrum and often at the margin of a simple peptic ulcer, may spread for a considerable distance in the mucosa, invading the tissue spaces and lymphatics and not remaining confined within the basement membranes of the glands. In some cases a dedifferentiation of varying degree has taken place, with the result that a varied picture is produced, and in whole or in part the lesion may assume the appearance of a small spheroidal-cell carcinoma. Intervening areas of mucosa not invaded by the growth, and perhaps showing intestinal metaplasia, may be present. A superficial or deep ulceration of the malignant tissue may be found. A. P. Stout described fifteen cases of this condition. In nine the growth started at the margin of a simple peptic ulcer and in five the growth itself was ulcerated. There was invasion of the muscularis, minimal in extent, in five cases only, but in seven metastases were found in the superior or inferior gastric glands. Other authors have described cases in which small but definitely larger foci of invasion beyond the muscularis mucosae were found at intervals. All Stout's fifteen

cases survived operation. One died of cancer 13 months after resection of stomach; of the remainder, four had survived for 3 years when his paper appeared, three between 2 and 3 years, three between 1 and 2 years, and three for less than a year. The prognosis in this type also would appear to be somewhat better than that obtaining in the average case of gastric carcinoma.

The distinction between carcinoma in situ, as defined above, and superficial spreading carcinoma of the stomach, rests therefore on a histological basis. In the absence of invasion of the muscularis mucosae some authors would place both lesions in the same category, though this is not strictly accurate. It would appear probable, however, that the former lesion may pass imperceptibly into the latter; but, as in cases of carcinoma in situ occurring elsewhere—for example, in the cervix uteri—a variable period, perhaps many years, may elapse.

In the detection of these early changes certain precautions have to be taken in the macroscopic examination of the resected stomach. It should be examined in the unfixed condition as soon as possible after removal. In some specimens there may be a reddish-brown discoloration or a slight puckering of the mucous membrane; in others, especially in cases of carcinoma in situ, nothing may be seen, the abnormal condition being discovered accidentally in the histological examination and perhaps starting at the margin of a gastric ulcer. A more extensive investigation of the stomach wall in the neighbourhood of gastric ulcers might reveal more of these cases—though they appear to be rare.

The more favourable results of operation reported in such cases indicate that early diagnosis is obviously desirable, but it is often a difficult matter and may be impossible. The clinical symptoms may be confused owing to the frequent association with gastric ulcer. X-ray examination may sometimes reveal a change in outline of the wall of the stomach and some interference with peristalsis. The use of the gastroscope and gastric biopsy may sometimes be successful. Of recent years cytological examination of the gastric mucosa has been practised and a variety of methods employed. Considerable experience is called for, but some workers—R. M. Graham⁴ and her colleagues, and R. O. K. Schade⁵—have succeeded in making early diagnoses.

MORE DEATHS FROM FOG

It is known that some increase in mortality accompanied a succession of severe fogs at the end of the nineteenth century, and there were occasional reports of similar occurrences during the first half of this century.¹ But it is only since 1949 that much notice has been taken of the great increase in the number of deaths that severe fog, especially

in London, brings in its train.² Now once more evidence has been presented of the toll taken of life. W. H. Bradley, W. P. D. Logan, and A. E. Martin³ have discussed the effect of the fog of December 2 to 5, 1957, on the Greater London area and J. A. Scott⁴ of its effect on the County of London. While it is impossible (and unnecessary) to be certain of the exact number of deaths attributable to the fog, there appears to have been an excess of between 800 and 1,000 deaths in Greater London, 400 of which occurred in the county council area (included in these figures are the 87 deaths of the Lewisham rail disaster). A. T. Gore and C. W. Shaddick⁵ suggest that there is a threshold level of four times the customary winter average of atmospheric pollution above which there will be an immediate increase in mortality. It is too early yet to say whether this hypothesis is generally true or whether a threshold value exists at all, but it is becoming increasingly clear that the rise in mortality occurs very early in the foggy period, and Bradley and his co-authors note that in the most recent episode it occurred before the atmospheric pollution had reached its maximum. Another point of interest is that deaths occurred among a younger group of persons than was the case with the fog of January, 1956,⁶ and Scott suggests that investigation would be worth while into the possibility of this having been related to the higher sulphur-dioxide content of the 1957 fog. Fogs undoubtedly cause sharp peaks in the mortality curve, but it is worth remembering that in the long run "normal" air pollution causes the greater loss of life. The Clean Air Act, 1956, will have the effect of reducing smoke and will probably thereby reduce mortality, but much remains to be done, not only in the study of the effect of air pollution on man and animals, but on the prevention of the pollution itself.

DEATH FROM OBSCURE CAUSES IN INFANCY

Though about 200 deaths of infants have been annually ascribed to accidental mechanical suffocation in England and Wales in recent years, many doctors have come to doubt whether the diagnosis is often valid. W. A. Brend⁷ was one of the first to study this question and to cast doubt on "overlying" by the mother as the frequent cause of death by suffocation it was then supposed to be. He commented, as others have done since, on the lack of adequate necropsy data. W. H. Davison⁸ made good this deficiency by carrying out post-mortem examinations in 1938-44 on 318 infants in Birmingham whose deaths were suspected to have been caused, at least in part, by asphyxia. Of these only 38 were found to have been so caused, and only 24 of them were ascribed to mechanical suffocation; the rest were ascribed to infections, mainly bronchopneumonia. Other investigators have confirmed the high incidence of infection as a cause of the deaths at first thought to be asphyxial, and many would agree with the comment made recently in our medico-legal columns⁹ that "a

diagnosis of accidental suffocation should not now be made unless there is an obvious mechanical cause for it."

In order to investigate these problems further a steering committee with Professor A. L. Banks, of Cambridge, as chairman was set up under the aegis of the Ministry of Health in 1953. Since then the members of this team have been carrying out necropsy studies on babies who died a sudden death between the ages of 2 weeks and 2 years in certain of the London boroughs and in the city of Cambridge and parts of the county. An interim report now presented¹⁰ shows the results in 64 London cases and 17 Cambridge cases. Of the 52 London cases examined histologically, 38 (73%) were found to have died of tracheobronchitis, 11 (21%) of bronchitis or bronchopneumonia, and the remaining 3 (6%) of septicaemia and gastro-enteritis. Of the 17 Cambridge cases 3 died of pneumonia (in the broad sense) and 1 of meningococcal septicaemia. In 13 cases the cause of death remained uncertain, but six of these showed inflammatory changes in the respiratory tract. Analysis of these deaths by the months in which they occurred showed them to be three times as prevalent in winter as in summer, while the proportion of males to females was 1.9 to 1. Both these statistical features are to be expected in deaths of babies from respiratory infection.

The investigation has now reached a point where the evidence so far gathered points to the need for more thorough virological study. Consequently the steering committee has formed a subcommittee under the chairmanship of Sir Samuel Bedson to pursue the viruses, and a full-time virus research worker is soon to be appointed. It is an important study and bids fair to unravel once and for all the exact causes of death in a type of case that is apt to be obscure to the doctor and particularly distressing to the parents.

TEENAGE SWIMMERS

At the recent Empire Games in Cardiff girls of from 14 to 19 years of age broke the world's records for the women's medley 4 × 110 yards relay swimming race and the women's 110 yards backstroke race. Why are such young girls capable of breaking swimming records presumably before at least some of them have developed their full physical strength? It has long been recognized that the peak age for best performances varies in different sports.¹ In the swimming events this seems consistently to be in the teens, especially so far as the women competitors are concerned. Are there any physiological factors to account for this or is it simply a training effect? The English girls in the successful relay team at Cardiff all trained for between 2 and 3½ hours a day and, with one exception, worked at school for the normal hours. The young Australian swimmers, whose success was also notable, trained for about the

same daily period. All divided the training into early morning and evening sessions. Most used the popular "controlled interval" method. This means that if the distance to be swum was one mile or 1,500 metres they divided the distance into 15 × 100 yards and swam each 100 yards at, say nine-tenths of their maximum speed, with a rest of about 10 seconds in between each 100 yards. The Australian swimmer Konrads would, for instance, swim 30 × 50 metres sprints at 32 seconds (his fastest time being about 27 seconds) with a 3-second rest between each sprint. This training technique is remarkable in its close resemblance to the "consecutive" quarter-miles run by Dr. Roger Bannister in his preparation for running the first under-four-minute mile.² But, apart from training, these girls also have inherent constitutional advantages in that they are of suitable somatotype for swimming. The combination of fat (endomorphism) for buoyancy and muscle (mesomorphism) for power and aggressiveness helps many young swimmers to achieve success. I. J. MacQueen³ has recently discussed the importance of somatotype in selection and training for sport. As puberty develops, the teenagers lose their puppy fat, develop more mature figures—and sink, or, at least, do not swim so fast. It has also been suggested that the younger of these girls have none of the worries of life (particularly boy friends) which may disturb the equanimity so essential to the expert swimmer.

"THE MEDICAL OFFICER"

For fifty years *The Medical Officer* has brought up-to-the-minute information to those who work in the public health service. This independent weekly periodical was founded by the late Sir George Elliston in 1908, and its golden jubilee number, dated September 5, 1958, has a commemorative article by Sir Allen Daley, who writes with respect and affection about the founder of the journal. Besides discussing the past Sir Allen also has some trenchant things to say about the future of the public health service. "The present position is," he writes, "that if local authorities are not prepared to pay the market price for good doctors they won't get them; preventive work will have to be tagged on to curative work, and the British public health service which has pioneered the world will die." Mr. Lewis Elliston, the present editor of *The Medical Officer* and eldest son of the founder, has taken the opportunity to recount the story of British public health as told in the pages of his journal from 1908 to 1958. The earlier part of this period was, as Sir Allen Daley says, the golden age of public health, but preventive medicine has still far to go, and public health workers may be confident that a journal which has served them so well in the past will successfully meet the changing needs of the future.

We record with regret the death on September 5 of Lieutenant-General Sir Bennett Hance, Director-General of the Indian Medical Service from 1943 to 1946.

WORLD FEDERATION FOR MENTAL HEALTH

ANNUAL MEETING IN VIENNA, AUGUST 24-29

[FROM A SPECIAL CORRESPONDENT]

For the second time in its ten years' life the World Federation for Mental Health held its annual meeting in this lovely city, at the invitation of its Austrian member society and under the patronage of the President of the Federal Republic. Dr. BROCK CHISHOLM, the retiring president of W.F.M.H., shared chairmanship with Professor HANS HOFF, who was later installed as president for the ensuing year, with Dr. PAUL SIVADON (France) as vice-president.

"Uprooting and Resettlement"

The growing stature of W.F.M.H. in the world was indicated by there being a special conference, within the meeting, of officials of governments, who shared in private sessions the main congress theme, "Uprooting and Resettlement," but who also collaborated with the informal non-governmental membership. The topic was peculiarly appropriate to the Austrian and Viennese scene. Ministers of the Republic and civic dignitaries who spoke at the opening session imparted realism and urgency to the proceedings. Austrians can be very proud of the part they have played over the centuries as the recipients and second home for great waves of migrants. The size of the problem was emphasized by the figure of 1.5 million of uprooted persons received and "processed" by Austria alone since 1945, including 180,000 Hungarians since 1956.

The annual meetings of W.F.M.H. are essentially devoted to the exchange of experience and method between practical workers—doctors, nurses, social workers, and social scientists. The meeting proceeds by discussion groups fed by a small number of "Keynote" addresses. Of these, Dr. BROCK CHISHOLM's sounded a sombre note of challenge. Humanity's chance of survival depended entirely on our capacity to stay the hands of those who are still playing with the destructive, suicidal fire of nuclear armaments—the ultimate insanity and mental health problem, especially in the light of recent scientific reports on the long-term effects of radiation on genetic mutation. This responsibility for our generation was unprecedented, since we were the first human generation to have both the secrets of nuclear power and the knowledge and insight of modern behavioural science into factors making for the warping of human personality. Our children and succeeding generations would judge us by the way in which we could at least initiate the difficult, untried task of changing attitudes from partial, antiquated systems of values, loyalties, and prejudices to an overriding responsibility for humanity itself. Dr. Chisholm instanced this by his own experience of parents who had preferred to let their own child die rather than let it be admitted to a hospital open to them but run by a hated rival religious body. Great nations squandered untold wealth on "raising dust on the moon" while 600 million out of 900 million children were inadequately fed, clothed, or housed. The way children were either coerced into the parental mould or allowed freely to outgrow their parents' narrower values seemed to Dr. Chisholm one of the keys to lessening unconscious hate and rebellion against life and all that this implied by way of defensive or antisocial behaviour.

Refugee and Host

Dr. MARIA PFISTER, of the mental health section of W.H.O. and an authority on refugee and D.P. problems, gave a most valuable paper on the interaction of refugee and host. The central theme was again the overwhelming importance of the clash between cultural values. The deep need to preserve identity (whether by individual or group) could lead to defensive regression. The group might become statically injured and uncooperative, while the at first well-meaning host community, perplexed by this unrecognized primitive

defence mechanism, might lose its good will. Similarly, the individual D.P. might soon project his fear and hate of the original persecutors on to his new, innocent hosts. The need, then, was for insight into the strength and depth of "tribal" culture patterns of both parties. In practice it called for skilled teams of catalytic liaison figures representing both host and migrant groups. Dr. Pfister's lecture gave a reassuring demonstration of the advances of socio-psychological knowledge in this field, though its application to the therapeutic task involved in large-scale resettlement, even of the voluntary migrant, remains difficult.

This point was elaborated in greater detail by Mr. ELFAN REES, of the World Council of Churches. We began to see the working of uniform mechanisms behind the variety of psychological and social behaviour symptoms in various refugee populations. The epidemic of refugees was likely to be with us for many years. As some were resettled, other waves broke. Thus, last year a million fresh refugees were added, mainly from Hungary, Yugoslavia, and Algiers. Mr. Rees confirmed that the difficulty of resettlement depended on the degree of cultural difference. He emphasized the explosive dynamic nature of refugee groups—a sort of third force of the "dispossessed," prone to rumour, propaganda, and irredentist revenge dreams, ever rejecting the possible and demanding the impossible. In some very poor countries the status of refugee was eagerly sought after: U.N. help made this the one certain free-meal ticket.

Psychology of the Migrant

The problem of the migrant's identity and self-esteem was closely linked to the general psychology of development and regression by Mr. ERIK H. ERIKSON, the American psycho-analyst. He showed by clinical examples the overlap between the unconscious motivations of the voluntary migrant, the more "real" persecution fears of the forced refugee and the prodigal son—the adolescent rebel and "angry young man." In this talk entitled "Identity in our Time," Mr. Erikson argued that the sense of being powerless drove all these categories of the dispossessed (whether by real or by fantasy agency) into mastery of their loneliness by fierce self-assertion or denial of dependence. Normally and in health a person's identity is echoed by the community's conferment of role and status. This orderly process the "outsider" missed. Thus he compensated by inner anger and even a paranoid feeling of omnipotence.

From this part of the programme there emerged a surprisingly clear statement of the malaise of our era: the millions of human beings without settled roots or status who could become the new world citizens with a less particularist self-perception, but who in practice behave singly or collectively like deprived children. Here indeed is a challenge to the disciplines concerned with mental health. Dr. H. STROTZKA (Vienna) modestly related his experience at the head of a multi-professional mental health team which took up this challenge during the acute Hungarian refugee crisis on the Austrian border.* This was a practical and deliberately oriented piece of action research, perhaps the first in history to apply preventive psychiatry to a mass phenomenon during peace-time. In the teeth of the usual opposition to psychiatry by the "common-sense" folk, the team succeeded in isolating and helping the more overt casualties, in being given access to obvious mental health crises, in establishing some selection and training in elementary human relations for camp staff and key figures, and in making useful observations.

The last day of the conference was devoted to reports and evaluation of the work of the numerous discussion groups, and to an address by Professor HANS HOFF on "Home and Identity." A concluding banquet marked the tenth anniversary of the World Federation. Dr. J. R. REES, the Federation's indefatigable director, reported on progress over the

*Details can be read in H. Hoff and H. Strotzka's *Die psychosoziale Betreuung ungarischer Neuflüchtlinge in Österreich, 1956-1958*. Hollinek, Vienna, 1958.

decennium. From 22 affiliated societies the membership had risen to 113 member associations representing a large part of the civilized world. The Federation had been consulted increasingly as the accredited body on a wide variety of topics by numerous U.N. agencies and other non-governmental international bodies. A Mental Health Year (analogous to the International Geophysical Year) was planned for 1960 calling for great efforts by member bodies and governments in all countries. Dr. Rees received an ovation by the assembled representatives of many national groups.

During the conference, Dr. H. V. DICKS (London) delivered the first Mary Hemingway Rees memorial lecture. This memorial was established by a trust to be devoted to biennial lectures on mental health and spiritual values. Dr. Dicks chose to speak on the striking resemblances between certain ancient Indian and Chinese thought and practice and some modern psycho-analytic concepts.

Vienna's traditional charm and hospitality added greatly to the benefits of an otherwise very serious meeting, of which only the highlights are briefly reported. There were some good mental health films and also visits to refugee camps and institutions.

Motoring News

SEAT COVERS

For the motorist who likes to improve the appearance of his car and yet make its interior last longer there can be few better buys than a set of seat covers. We all know how luxurious even a cheap car can look if it has some attractive seat covers, and for an outlay of about £7 this can be very simply achieved. Seat covers perform several functions in that they protect the original upholstery, be it real leather or cheap leathercloth, from the ravages of dogs, young children, or untidy owners. They protect the suits of professional men from the shininess caused by rubbing against leather or plastic. They also stop dirt and stains from going into the upholstery, which is not so easily cleaned as detachable covers. Slippery seats also can often be cured by the fitting of good fabric covers, thus adding to the comfort of passengers on a long journey. Loose covers therefore have a definite value in keeping up the second-hand value of the car by protecting the upholstery.

There are so many different materials on the market today that it is not easy to choose the most suitable. Woven materials are generally best, though felt is perhaps the least expensive and will wash well without losing its shape. Rayon is suitable for very hard wear and where there is much dirt; it is an excellent material for those who must transport dogs in the car, for it can be wiped clean with a damp cloth. It is cold to the touch, however, and is not ideal for winter use. Natural fabrics such as the varieties of Bedford cord and pure wool give hard wear and warmth, and the same applies to the various imitation furs such as leopard and zebra. A less expensive material is cotton duck, which, though it is not thick, is warm in winter and cool in summer. In recent months transparent plastic has come into fashion, particularly on coupés and open cars, so as to show the original pattern of the upholstery and yet render it showerproof. While being reasonably hard-wearing, these plastics do not "breathe" like a normal cloth, and they are therefore uncomfortable in hot weather.

Touring Spares

If you are among the happy minority of motorists who have not yet embarked on a summer holiday, you may still be sorting out your baggage and prowling round your garage for useful items to add to the tool kit of your car in case of emergencies. The average tool roll provided with a new

car, if it is a popular model in the low or medium price range, is usually inadequate for any but the simplest of repairs. One item in particular which is often omitted from such an outfit is a spanner for adjusting the small nuts holding the contact-breaker points. A 2BA electrical spanner is therefore desirable as being the most useful, but a set including 2, 3, 4, and 5BA can be obtained cheaply and will cover all requirements. A small screwdriver with an insulated plastic handle and a large roll of insulating tape, wrapped to prevent oil from destroying its adhesive properties, should also be carried. Likewise a length of heavy-duty electric cable with some crocodile clips can be useful for temporary repairs where the wiring has failed in some inaccessible spot.

Spare fuses or fuse-wire, contact-breaker points, and spare parts for the water pump, if fitted, can often prevent hours of delay at some wayside garage should the correct pattern of parts be unobtainable. A tyre pressure gauge and a grease gun should, of course, be in the tool kit already, as well as a plug spanner. One item which is often omitted from a seemingly comprehensive tool kit is a powerful chrome-vanadium ring spanner for cylinder head nuts. If you have to change a gasket the usual cheap black spanner will not shift a nut done up to 45 lb./ft. or more. Mechanical spares such as fan belts, a spare plug, condenser, and a cylinder-head gasket should always be carried, and, if you want to be really independent, a half shaft and a coil should see you through any emergency. When carrying gaskets, however, remember to see that they are carefully stored in a position where they will not be damaged.

Yellow Lights

Within the past few years more and more British motorists have come to appreciate the advantages of yellow lights. Those who have driven in France, where yellow headlamps are compulsory, may have noted the advantage of lack of dazzle which yellow bulbs offer. There is very little difficulty in obtaining coloured bulbs to suit any normal British-made car, especially those of recent manufacture.

They cost slightly more than the white ones, but their light is much softer on the eyes both for the driver of the car to which they are fitted and for the drivers of oncoming cars. They are also better for use in fog and for town driving on dipped beams, as there is less dazzle from shop windows and other reflecting surfaces. The French Government found that it was easier to specify yellow bulbs for all vehicles than to go to the trouble of testing the headlamps of individual vehicles, and the system seems to be satisfactory.

The only road users who might find cause to complain are the owners of fast sports cars, for whom yellow lamps mean a shorter beam and therefore a smaller margin of safety at high speeds. This could be overcome by using lenses for a long narrow beam and by fitting supplementary lamps for kerb illumination. The normal road user, however, would find the more restful yellow beams sufficiently penetrating for all types of night driving, while the dipped beam could be used on busy arterial roads without there being any question of offending oncoming traffic, as is often the case with present double-dipping white lights. In many other European countries motorists are following the French example, for dazzle is a well-known cause of road accidents, and anything which counteracts this is surely worthy of trial.

Neurochirurgia is published by Georg Thieme, Leipzig, as a supplement to *Fortschritte der Neurologie und Psychiatrie*. It contains articles in English, French, or German, in each case with a summary in the other two languages. For the present, two numbers of *Neurochirurgia* will appear each year at an annual subscription of DM. 18 (DM. 16.20 to subscribers to the *Fortschritte*).

The public do not credit smoking with any therapeutic effects except those of soothing the nerves of the addict

and curbing an excessive appetite for food. If they assume that tobacco smoke contains some stimulating principle they are well justified, and propaganda designed to obscure this fact could hardly be called education, nor is it necessary or justifiable in any way. It would seem, on the contrary, a dangerous and ultimately futile attempt on the part of the medical profession to deceive both itself and the public.—I am, etc.,

London, S.W.10.

Ergometrine with Hyaluronidase

SIR,—The studies on the puerperal uterus which Mr. W. J. Garrett and I reported (*Journal*, July 19, p. 138) were designed to measure objectively and compare the speeds of action of ergometrine when given by (i) intravenous injection, (ii) intramuscular injection, and (iii) intramuscular injection with added hyaluronidase. It was on a comparison of these speeds that we based our opinions as to the merit of routinely using intramuscular ergometrine with hyaluronidase at crowning of the head.

Mr. E. G. Jonas (*Journal*, August 16, p. 450) raises quite another issue, which I respectfully suggest is hardly relevant, when he implies that similar studies carried out in the second and third stages of labour might give very different results. In fact, there is little evidence to support this contention, and tocographic experiment shows that there is no significant difference between the speed of action of oxytocics in labour and in the early days of the puerperium. But, even allowing that the response to ergometrine is "at its zenith during labour," I would point out that it is the comparative speed of action of the three injections which is important. The addition of hyaluronidase to the injection undoubtedly accelerates the action of ergometrine, but the latent period is only reduced by 30%, while intravenous injection is still five times as rapid in action. It was in the light of these results that we questioned whether the adoption of the method as a routine for use by midwives was justified.—I am, etc.,

Oxford.

MOSTYN P. EMBREY.

Congenital Deaf-mutism

SIR,—The article by Dr. J. McKenzie on the aetiology and treatment of congenital deaf-mutism (*Journal*, July 26, p. 201) is so full of inaccuracies and statements contrary to physiology and clinical experience that one would need twice as much space as the article itself to refute them. Five children, including four who according to responses to air conduction audiometry were almost totally deaf, were examined by an audiometrician. Because there was also a response to sensations as produced by the oscillator for bone conduction audiometry at very much smaller intensities (as compared with the air conduction responses) Dr. McKenzie concluded that he made a completely new discovery—namely, that these children suffered not from a congenital perceptive but from a conductive deafness. He had no other evidence, but it was enough for him to formulate a theory. But these theoretical considerations are based on false assumptions. It is notorious how careful one must be with bone conduction tests in children, and how even in the older ones, when very deaf, the responses can be very unreliable.

Let us now analyse these audiograms. It is interesting to see that in four of them only a residual hearing for low frequencies is registered by air conduction, and that there is quite a significant variation in these, when the four audiograms are compared. But the response to the bone conduction oscillator is almost identical in all the cases. (If you take, for example, the responses in the right ear only, registered at twelve points, only at two points is there a slight difference. Otherwise the curves are absolutely identical.) This, of course, although not only this, immediately casts great doubts upon the validity of these tests. I wonder how Dr. McKenzie would explain it.

I suggest that the responses to the bone conduction oscillator do not represent sensations of hearing but are responses to the vibratory elements always contained in low frequency sounds of

high intensity. I would go even further and say that there is a possibility that the responses to sounds delivered via the earphones, when there is only a residual response to these low frequencies at high intensities, are only reactions to the vibratory element in the sound, and that these children often are in fact totally deaf. I am saying this from clinical observation and confirmation by histological evidence. I had the opportunity to test and observe a little girl, who was very deaf, from the age of 2½ to 3½. She responded to a very loud drum from 6 to 7 ft. (1.8 m. to 2 m.), to a loud xylophone of 500 c/s from 2 to 3 ft. (61 cm. to 0.9 m.), and to some other loud sounds of low frequency. This girl died later and the inner ear was examined histologically. There was no organ of Corti in any part of the cochlear canal; there was no vestibular membrane; also the nerve fibres entering the cochlear canal were very sparse. The aetiology was a well-known type of hereditary deafness. Undoubtedly a totally deaf individual can respond to the vibratory elements of low frequency sounds even in free field, and of course even better when the sound is applied by an oscillator on the skull. When these people are tested for bone-conduction hearing it is frequently difficult (even in some adults) to explain the difference between sensations of hearing and vibration, especially when they have never experienced true sensations of hearing normally. Also frequently there is the difficulty in communication which prevents a full explanation of the differences.

Of course the crux of the matter in the case of Dr. McKenzie's article is in his statement that careful attention was given to the possibility of the child confusing hearing with vibration. Could he explain how this was done in detail? And also the method of audiometry? For some years it has been possible to carry out reliable threshold audiometry in small children, in many cases from the age of 2½, and almost as a routine from 3½. What was the type of oscillator used? What was the signal the children were given during the test which indicated a reliable response? In an article entirely based on the results of a method of examination a clear and careful description of the method employed is essential.—I am, etc.,

Harrow.

L. FISCH.

Suffocation in Infancy

SIR,—I welcome Dr. J. Shackleton Bailey's letter (*Journal*, July 12, p. 104), and I agree with him that reconsideration of mechanical suffocation as the cause of many of the sudden deaths in infancy is urgently required. Unlike the pathologists mentioned in Dr. W. H. Davison's letter (*Journal*, July 26, p. 248), I have found by post-mortem, histological, and bacteriological examination an adequate natural cause of death in only about 25% of these infants. It is, I realize, a matter of opinion, but I am not persuaded that the finding of occasional mononuclear cells (some of which I think are desquamated bronchial epithelial cells) in the lung alveoli of a robust-looking infant of previous good health is adequate evidence of death from pneumonia. In the remainder of my cases, observed over the last six years, the infants were found in circumstances in which death could have been caused by suffocation. Indeed, in many cases suffocation seemed the obvious explanation of the observed circumstances. In my opinion the pathological findings were consistent with death from asphyxia.

I was therefore concerned to read that your paediatric correspondent (*Journal*, July 12, p. 111) seemed to suggest, if I understood him correctly, that asphyxia from overlying or soft pillows is an old wives' tale. I submit there is insufficient evidence to support such an opinion. I am also concerned in case such a view comes to the notice of, and is accepted by, parents; if this should happen I fear more bed and cot deaths will occur, not fewer. My experience leads me to think that the right place for a baby to sleep is in a separate cot with a firm mattress, and without a pillow until the age of 1 year, and that he should never be left unattended with a bottle in his mouth. I personally believe that if these simple conditions, observed in the children's wards of the Darlington Memorial Hospital, were put into practice in the home, many of these tragedies would be prevented.—I am, etc.,

Darlington.

J. TREGILLUS.

Perforated Ulcer in Pregnancy

SIR,—The publication of the memorandum by Mr. Martin Horwich in the *Journal* of July 19 (p. 145) prompts me to report the following case:

On December 8, 1957, a para 3, aged 28 years, who had been delivered of a live male infant on the previous day at home, was admitted as an emergency to the ward complaining of severe abdominal pain. The pregnancy was apparently quite normal until 48 hours before delivery, when she developed a mid-abdominal pain which she had never experienced before. This was accompanied by nausea, and diarrhoea on one occasion. Labour progressed normally apart from being accompanied by this pain, which was maximal in the hypogastrium, and delivery was uneventful. She vomited several times during labour, but no blood was noticed. The following day the pain became more severe and was accompanied by referred pain to the right shoulder tip.

On examination she appeared to be shocked and in severe pain. Her temperature was 98.2° F. (36.8° C.), B.P. 120/90, and pulse 98. Her abdomen was extremely tender, markedly so in the right hypochondrium, but there was no guarding or rigidity. The uterus was well contracted, being 5 in. (12.7 cm.) above the symphysis pubis. Shifting dullness was elicited and no bowel sounds were present. A provisional diagnosis of free fluid in the peritoneal cavity was made; a possible origin was thought to be a ruptured uterus. The pulse rate rose to 120 beats per minute during the following two hours, and a laparotomy was performed by Mr. C. T. F. Ealand, revealing a considerable quantity of bile-stained fluid in the peritoneal cavity and a large anterior perforation of the first part of the duodenum. Recovery was uneventful and she was discharged home a fortnight later.

As pointed out by Mr. Horwich, most cases of perforated ulcer which occur during pregnancy have a definite history, but this patient had no previous symptoms of abdominal pain or dyspepsia. Finally, I should like to draw attention to the fact that there was no guarding or rigidity of her abdomen. The absence of this classical sign of peritoneal irritation in the puerperium must be stressed, since failure to recognize this may result in serious delay in establishing a diagnosis.—I am, etc.,

Windsor.

I. G. ROSS.

Posture and Blood Pressure in Pregnancy

SIR,—A patient we thought to be suffering from early toxæmia of pregnancy had had frequent blood-pressure readings taken in the lying-down position, until the occasion when for no particular reason the blood pressure was taken in her living-room while she sat at a table. This time the readings were unexpectedly low, and normal. They were repeated a few minutes later when she was lying on her bed, and again the abnormally high readings were obtained. This state of affairs continued, so that if we relied on the readings taken while she was lying down we had to regard her as a case of toxæmia, but if we heeded only the readings taken while she was in the sitting position we could say she was normal.

Since this chance observation we have taken many double readings in expectant mothers who were first sitting, then lying down (or vice versa), and have in several cases, but not lying all, found similar differences between the sitting and lying readings. In a few patients the two sets of readings were the same, and in one case the lying pressures were lower than the sitting. Having been unable to find any reference to this phenomenon in several important textbooks, we would be interested to know if other observers have encountered it and be grateful for views as to its significance: can the higher readings be ignored regardless of the position with which they are associated?—We are, etc.,

P. R. BOUCHER.

MARGARET J. TURPIN.

Winfrith, Dorset.

Why are Medical Journals so Dull?

SIR,—Were it not for the fact that one remembers Dr. Richard Asher as the author some years ago of that stimulating article "Myxoedematous Madness," one would be inclined to take him at his word and agree with him that some, at any rate, of his present article (*Journal*, August 23, p. 502) was more than "probably irritating." One suspects Dr. Asher of writing very largely with his tongue in his

cheek. To say that style is everything and all the rest—syntax, grammar, spelling, etc.—do not matter is a heresy of the worst kind.

Is style so easy to acquire? Buffon, in what is now almost a cliché, said: "Le style, c'est l'homme." Anybody, apparently, except those who write learned articles in the medical journals can write good plain English, but how many people have individuality—style in other words? Dr. Asher evidently thinks that style consists in saying what is outrageous, highly controversial, or what you will. Style is only acquired, if ever, by any given individual, through wide reading, and even that won't always do it.—I am, etc.,

Brighton, 5.

G. L. DAVIES.

REFERENCE
Asher, R., *Brit. med. J.*, 1949, 2, 555.

SIR,—What a fine and worthy example of the art of the editor you gave us in publishing Dr. S. Levin's enlightening article on "Stool-gazing," following on Dr. Richard Asher's true lament on "Why are Medical Journals so Dull?" You did make the *Journal*, August 23, a brighter one. Even Dr. Asher must admit it was a subtle appreciation of his article.

Now that you publish a list of new drugs, maybe you can help the avid reader with a list of new "words," with explanatory notes?—I am, etc.,

London, W.1.

M. J. FENTON.

Coudé Catheter

SIR,—The letter from Mr. Hamilton Bailey and his colleagues (*Journal*, August 23, p. 513) has caused the research staff of *The Leech* considerable disappointment and distress, and the labelling of a "biography written in a serious and restrained vein," to use their own words, as "a hoax," "a fabrication," and "a mire" is unexpected from such distinguished men of medicine. However, the recognition given by the rest of the medical world has been most encouraging: a professor at one London medical school writes: "... an important contribution ... congratulations on a fine piece of work." This will hearten us to continue to publish our researches.—I am, etc.,

Cardiff.

D. M. J. WILLIAMS,
Editor, *The Leech*.

SIR,—I, too, share Dr. Peter Birkett's sorrow (*Journal*, August 30, p. 567) that great names have been dragged into the mire. However, one does not further the cause of historical accuracy by exposing one fabrication whilst condoning another. Fortunately every student knows that the real benefactor has proved to be, not Coudé, but his half-brother Bicoudé, who, as Mr. Clifford Morson (*Journal*, August 23, p. 513) well remembers, declined the presidency of the Société Internationale d'Urologie as a protest against the opening of Mercier's Bar.—I am, etc.,

London, W.1.

HOWARD G. HANLEY.

SIR,—A few years before the amusing episode narrated by Mr. Stephen Power (*Journal*, September 6, p. 640) I witnessed the following incident in the surgical out-patient department of the London Hospital.

RUSSELL HOWARD: "How would you relieve this patient's retention of urine?"

STUDENT: "I would pass a catheter."

RUSSELL HOWARD: "What type of catheter?"

STUDENT: "A Coué catheter, Sir."

RUSSELL HOWARD: "Oh! And I presume as you passed this catheter you would say to the patient: 'Every day and in every way I am passing my water better and better.'"

—I am, etc.,

Sholden, nr. Deal.

HAMILTON BAILEY.

* * This correspondence is now closed.—ED., *B.M.J.*

POINTS FROM LETTERS

Smallpox Vaccination

Dr. N. D. WAYNE (London, E.1) writes: In over 17 years of vaccinating people I have noticed, consistently, the appearance of a local skin reaction within ten minutes of completion of the act, when the lymph has dried. The area of scarification, or now of multiple pressure, becomes slightly raised and puckered. In all these cases the vaccination is invariably positive.

Obituary

RUPERT WATERHOUSE, M.D., F.R.C.P.

Dr. Rupert Waterhouse, who practised in Bath and was for many years a leading consultant there with a special interest in clinical pathology, died at the Royal United Hospital, Bath, on September 1 in his 86th year.

The youngest son of Dr. John Hodgson Waterhouse, Rupert Waterhouse was born at Sheffield on January 15, 1873. He was a descendant of Sir Gilbert Waterhouse, a nephew of Dr. T. Waterhouse, surgeon to Sheffield Royal Infirmary, and grandson of John Hodgson, a surgeon at Birmingham. From the Collegiate School and Wesley College, Sheffield, he went on to St. Bartholomew's Hospital, qualifying in 1897. After holding a resident appointment at the Royal Hospital, Sheffield, he graduated M.B. in 1900 and proceeded M.D. in 1903. He took the M.R.C.P. in 1908 and was elected F.R.C.P. in 1929.

Dr. Waterhouse first came to Bath in 1901, when he was appointed resident medical officer to the Royal United Hospital. Two years later he held a similar post in the Royal Mineral Water Hospital. Appointed first curator of the museum and pathologist at the Royal United Hospital, he later became an honorary physician to that hospital and to the Royal Mineral

Water Hospital. He was the author of many papers, mainly on rheumatological subjects, and his description of the clinical entity of acute suparenal insufficiency due to bilateral renal haemorrhage was published in 1911; it is now known throughout the world as the Waterhouse-Friderichsen syndrome.

A Territorial, Dr. Waterhouse served throughout the first world war in the R.A.M.C. in Gallipoli, Egypt, Palestine, and France. Serving first with the North Somerset Yeomanry, he commanded the 2nd South-West Mounted Brigade field ambulance for two years, and in 1920 was gazetted to command the 4th Southern General Hospital.

When he returned to Bath he practised mainly as a consultant in clinical pathology, and at the Annual Meeting of the B.M.A. in 1925 he was vice-president of the Section of Pathology and Bacteriology. Besides his hospital appointments in Bath he was on the staff of several hospitals in the neighbourhood, including the Victoria Hospital, Frome, the Trowbridge and District Hospital, and the cottage hospital at Chippenham. A founder member and past-president of the Bath Clinical Society, he was chairman of the Bath Division of the B.M.A. in 1923-4, and president of the Bath and Bristol Branch in 1928-9.

Dr. Waterhouse leaves a widow and a son and daughter.

G. D. K. writes: During his latter years Dr. Waterhouse was much handicapped by deafness and by lameness resulting from osteoarthritis and Paget's disease of the hip. In spite of this he was never heard to complain and retained his sense of humour and dry ready wit until the end. He will be remembered as one of the great old-time physicians of

Bath, and one who was more interested in the facts of medicine and their application to human beings than to their financially gainful possibilities. He stood for all that was honourable in the medical profession and had no use for any mumbo-jumbo. He was a reliable friend, never at a loss for a humorous answer to any question, and, although for a long time he had not been able to take an active part in medical matters, he will be very greatly missed by his colleagues and many friends.

K. S. LASHLEY, M.S., Sc.D., Ph.D.

We record with regret the death of Professor K. S. Lashley, formerly research professor in neuropsychology at Harvard University. He was 68.

Karl Spencer Lashley was educated at the Universities of West Virginia and Pittsburgh, where he graduated Sc.D. in 1911. After a few years as a teaching fellow at the University of Pittsburgh, he moved to Johns Hopkins and then to the University of Minnesota, where he became professor of psychology. Appointed to the equivalent position in Chicago in 1929, he became research professor at Harvard in 1937. He also held the directorship of the Yerkes Laboratories of Primate Biology at Orange Park, Florida, where much of his most notable work was done. On giving up his post at Harvard in 1955 he was appointed emeritus professor.

Lashley made many important contributions to psychology and neurophysiology, but he was best known for his work on animal behaviour. He was an honorary member of the British Society for the Study of Animal Behaviour, and in 1951 his outstanding work was recognized by his election to foreign membership of the Royal Society.

We are indebted to Professor O. L. ZANGWILL for the following appreciation: Professor K. S. Lashley won an international reputation for his studies on brain mechanisms and intelligence. Trained in psychology, Lashley worked with Dr. J. B. Watson at Johns Hopkins University and became a leading spirit in the Behaviourist movement. But he was quick to see the limitations of doctrinaire Behaviourism and had little use for speculative theory. His ideal was a science of behaviour firmly grounded in comparative neurology. That this ideal no longer seems incredible is the true measure of his achievement. Lashley's strength derived from his masterly synthesis of physiological and psychological methods of inquiry. From the neurophysiologist he took over the method of ablation; from the animal psychologist the use of systematic training techniques such as the maze and the discrimination box. As a result of this "combined operation" it became possible for the first time to assess the effects of brain lesions on behaviour in terms of measurement. Crude though measurements of behaviour may be, they at least make possible systematic comparison of pre- and post-operative performance in animals. In this way Lashley inaugurated a new epoch in the comparative study of the brain.

As is well known, Lashley's experiments led him to the view that cortical function is considerably less specialized and less narrowly related to specific structures than had formerly been supposed. Although habits involving a single sense modality—for instance, visual discrimination—were found to be impaired or lost only after ablations limited to the corresponding cortical projection area, more complicated tasks were found to be affected by lesions anywhere in the cortex. Thus, in the case of maze performance in the rat, impairment was found to follow lesions in any cortical area and the extent of the impairment proved to be broadly proportional to the extent of the lesion. Lashley therefore postulated a very considerable degree of equipotentiality within the cortex and a principle of mass action governing its efficiency. Although later work has cast doubt on both these assumptions, Lashley's thorough experimental work will long remain as a major contribution to neurology.

Although Lashley made no direct contribution to clinical problems, his work has had great influence. His study of the motor cortex published in *Brain* in 1921 and his later work with Clark on cortical cytoarchitectonics have become classical. Lashley was also widely informed in the literature of aphasia, agnosia, and apraxia, and took a lively interest in the work of such men as Goldstein and Head. If in an indirect manner, his work has had great influence on our modern conceptions of cerebral function in man. Lashley visited this country on several occasions and is particularly remembered for his contribution to the Symposium on Physiological Mechanisms in Animal Behaviour held at Cambridge in 1949. Here he impressed everyone by his remarkable grasp of the subject and his extraordinary quickness of mind.

MARGARET H. R. ROBINSON, M.B., Ch.B.

D.T.M.&H.

Dr. Margaret H. R. Robinson (formerly Young), who had worked in Hornsey for nearly fifteen years as medical officer for maternity, child welfare, and school health, died at Hampstead General Hospital on July 25 after a short illness. She was 59 years of age.

Margaret Helen Rattray Young was born on August 21, 1898, and was a medical student at St. Andrews University, where she graduated M.B., Ch.B. in 1922. She took the D.T.M.&H. with the intention of going to the tropics, but instead she became bacteriologist at the Central Public Health Laboratory, Utrecht, Holland, a position which she held for two years. Much of her time there was given to the investigation of tropical diseases, but she also worked on Weil's disease and post-vaccinal encephalitis. While in Utrecht she met her future husband, Dr. Conmar Robinson, and for the next fifteen years devoted her life to her family. She then returned to work as assistant medical officer of health to the Hertfordshire Council and two years later to the Hornsey Borough Council. She served Hornsey well for fourteen years, bringing to the personal health services of the borough a wide knowledge of the preventive aspects of child health and a deep understanding of the psychological problems of young people.

A friend writes: Those who were privileged to know "Greta" Robinson have indeed lost an exceptional friend. "Vital" is the word that describes her best. Lively, kind, energetic yet thoughtful, she was congenial through her wide interests to many utterly different people. From her student days her beautiful soprano voice made her welcome in musical circles; she read widely, and travelled not only along well-known routes but also in by-ways, and for these journeys she and her husband would first learn the language of the country they were to visit. Besides Dutch, she spoke French and Spanish fluently, and some German and Italian. She loved to entertain, and was a charming hostess at whose happy home young and old would meet the very people they wanted most to see. Now to these memories we have to add that of the gay courage with which she faced her terminal illness. The sympathy of her many friends goes out to her husband and her son and daughter (both members of her profession) in their sorrow.

J. S. du TOIT, M.D., F.R.C.S.Ed.

Mr. J. S. du Toit, consulting ophthalmic surgeon to the Groote Schuur Hospital, Capetown, died at his home in that city on August 3. A past president of the Medical Association of South Africa, he was also for very many years its honorary treasurer. He was 72 years of age.

Jacobus Stephanus du Toit was born at Worcester, Cape Province, on March 5, 1886, and was educated at Worcester Boys' High School, at French Hoek, and at Victoria College, Stellenbosch. He studied medicine at Edinburgh University, and graduated M.B., Ch.B. in 1912, proceeding to the M.D. and two years later. In 1915 he was elected F.R.C.S.Ed. After some four years of postgraduate study in ophthalmology and neurology in London, he returned to South Africa and

set up in private practice as an ophthalmic surgeon in Capetown in 1916. After setting up an ophthalmic clinic at the Capetown Free Dispensary he was elected to the staff of the Somerset Hospital, which was later transferred to Groote Schuur Hospital. From 1937 to 1949 he and Dr. A. W. S. Sichel served as joint chiefs of the department of ophthalmology at the hospital and joint senior lecturers at the university. For twenty-one years he was ophthalmic surgeon to the School for the Blind at Worcester.

Dr. du Toit was for many years honorary treasurer of the Cape Western Branch of the British Medical Association, and was president of the Branch and chairman of the Capetown Division in 1929-30. Since 1929 he had been honorary treasurer of the Medical Association of South Africa, which in 1952 awarded him its gold medal for distinguished services to the medical profession and the Association. Four years later he was elected President of the Association. Dr. du Toit was a member of the council of the University of Capetown for thirty-two years and a director for twenty-five years of the Nasionale Pers Beperk. For many years he was interested in farming and owned a farm at Durbanville. In 1916 he married Miss Emmeline J. Steyn, youngest daughter of President M. T. Steyn, of the Orange Free State, and she survives him together with the three daughters of the marriage. His only son died in 1935.

G. V. T. McMICHAEL, O.B.E., M.B., Ch.B. D.P.H.

Dr. G. V. T. McMichael, formerly medical officer of health for Paisley, died at the Western Infirmary, Glasgow, on August 22. He was 71 years of age.

George Vert Thomson McMichael was born on February 6, 1887, at Edinburgh, where his father was for many years a leading member of the city council. After receiving his schooling at George Watson's College, he studied medicine at Edinburgh University and graduated M.B., Ch.B. in 1911. In the following year he obtained the D.P.H. of the Scottish Royal Corporations. Soon after graduation he entered the public health service, and was assistant medical officer of health under the Renfrew county council until 1921. During the first world war he served for four years in the R.A.M.C., first as a regimental medical officer and then for some time in an administrative post in a general hospital in France, where his great gift for organization brought him promotion to the rank of major. In 1919 he returned to his civilian duties, and in 1921 he was appointed medical officer of health to the burgh of Paisley, a position he continued to occupy for the next 32 years. A member of the British Medical Association for 45 years, he was chairman of the Renfrewshire and Buteshire Division from 1931 to 1934. He leaves a widow, one son, and two daughters.

C. S. B. writes: During the time George McMichael was medical officer of health for Paisley he devoted all his energy and talent to improving the health services of the town, an aim in which he was brilliantly successful. An achievement that gave him great satisfaction was the establishment of the first municipally controlled maternity hospital in Scotland. He was the moving spirit also in the building of Paisley's very modern infectious diseases hospital. When first opened, almost 30 years ago, it was admitted to be—thanks to George McMichael's planning—one of the finest hospitals of its kind in Britain. Many others have been modelled on it, with its widely spaced pavilions, its well-equipped kitchens, and its admirable ancillary departments. George McMichael was a man of many activities. Among the positions he filled during his public career were those of president of the Royal Sanitary Association of Scotland, chairman of the Scottish division of the Society of Medical Officers of Health, and chairman of the Paisley and District Hospital Management Board. His good work was recognized in 1950 by his appointment as O.B.E. He suffered a long illness with the most admirable patience and cheerful courage.

HUGH MILLIGAN, M.B., B.Ch., D.P.H.

Dr. Hugh Milligan, who was in general practice at Whittle-le-Woods, near Chorley, Lancashire, died suddenly on August 23 while on holiday in the Isle of Man. He was 49 years of age.

Hugh Milligan was born at Holywood, Belfast, on January 18, 1909, and was educated at the Queen's University of Belfast, where he graduated M.B., B.Ch. in 1932. Two years later he obtained the D.P.H. He was in practice at Oldham before moving to Whittle-le-Woods in 1936. A founder-member of the Chorley and District Society for Mentally Handicapped Children, his work and interest in the society will long be remembered. In 1955 he was appointed police surgeon for the Chorley division of the Lancashire constabulary. He leaves a widow and three children.

W. McE. writes: It was as a village G.P. that Hugh Milligan earned for himself an outstanding reputation. A busy man with a large practice, he somehow managed to get to know every one of his patients, and few and far between were the ones whose background he did not remember or whose Christian name he did not use. He gave himself unsparingly to his work, and people in all walks of life valued greatly his skill, patience, advice, and friendship. Perhaps the secret of his success was his keen interest in people as individuals, and he inspired their confidence and trust because they knew he really cared. The fact that the whole village was grief-stricken at the news of his death and that something like a thousand people crowded the parish church at his funeral is an indication of the love and esteem in which he was held. This brief account would be incomplete without some mention of Hugh Milligan's personal courage. Although never very strong, he never allowed his disabilities to weigh heavily upon him, and only in extreme necessity did he allow any interference with his work. Two years ago he was forced to spend some time in hospital, yet even there he was fretting to be out and about, anxious for the welfare of his patients rather than his own. The prospect of death held little fear for him (for he had spiritual depth), but he could not bear to think of his patients looking to him in vain. His courage was impressive and his sense of humour a blessing both to himself and others. His name will long be honoured in the place where he worked: may he rest in peace.

J. C. CAMPBELL, M.B., Ch.B., F.R.C.S.Ed.

Mr. John Campbell, an ear, nose, and throat surgeon in Carlisle, who died at Cumberland Infirmary on August 26 after a short illness at the age of 36, will be greatly missed by his many friends, patients, and colleagues in Carlisle and the south-west of Scotland.

John Carr Campbell was born at Inverness on December 6, 1921, the son of a well-known doctor, and throughout his life he retained a great affection for Inverness and the Highlands. At Loretto School and Edinburgh University he was well known as a piper and for his prowess at rugby, which he played with enthusiasm and skill. After graduating M.B., Ch.B. in 1944 he held the appointment of house-surgeon at Leith Hospital, and then had a short spell in practice with his father before joining the R.A.M.C. His service in the Army was essentially spent in India during the troublesome times of 1947. He then returned to Edinburgh and pursued his main interest—ear, nose, and throat surgery—under the late Dr. G. Ewart Martin. During the tenure of his appointment at the Royal Infirmary he became a Fellow of the Royal College of Surgeons of Edinburgh in 1950. Shortly afterwards he went to Carlisle as a registrar, and after a short period in London was appointed a consultant to the East and West Cumberland groups of hospitals and to the Dumfriesshire hospitals.

A. B. MacL. writes: John Campbell's work was of the highest standard and he was a skilled operator. He had a very happy way of making friends with his patients, sparing no efforts to ensure their well-being in the widest sense, and yet he had a modest view of his own capabilities.

He was perhaps at his best with children, who, shrewd judges of character as they are, loved him and would do anything for him. A speaker of considerable wit and wisdom, he was often in demand on social occasions, and played a valuable part as the secretary of the Carlisle Medical Society. His interests were sailing, in a boat which he built himself, and in the occasional week-end in his caravan, in which he took great pride and in which he was able to share his leisure with his family. We have lost a well-loved, faithful, and generous friend, and our sympathies go to his two small sons and his wife, who is also a doctor.

DANIEL P. O'BRIEN, M.D.

Dr. Daniel P. O'Brien, who had been administrator of the medical science and research division of the Rockefeller Institute for Medical Research, died at Acapulco, Mexico, on August 16.

Daniel P. O'Brien, a native of Torrington, Connecticut, was born in 1894. He graduated in medicine from Johns Hopkins University in 1920. For some years before the second world war he worked as the European representative of the Rockefeller Foundation, and for the greater part of the war he was in London, where he did much to foster Anglo-American friendship.

A. D. writes: News of the death of Pat O'Brien will strike a sad note in the hearts of his many British friends. After the fall of France he moved the European office of the Rockefeller Foundation from Paris to London. He took a flat in St. James's, lived among us, and shared stoically and with humour our discomforts. In 1938 he had joined the Athenaeum Club: he was often there after he came to live in London, and he retained his membership until his death. Always cheerful and optimistic, he visited incessantly the various academic institutions receiving, or desirous of receiving, grants from his Foundation. His advice was freely sought and generously given. He had the ready and genial friendliness so often found in those of Irish extraction. There was always, until his vision began to fail, a merry twinkle in his strikingly blue eyes. He was a physiologist by training, and his later interests covered every branch of medicine and science. He knew all the leading scientific workers in Europe and told fascinating anecdotes of their idiosyncrasies. He was active in bringing together American and Canadian doctors then serving in this country and their Service and civilian colleagues here. My last meeting with him was in the ophthalmic ward of the Johns Hopkins Hospital, Baltimore, where he was under treatment for detached retina. He faced resignedly the prospect of complete loss of his sight. He did, however, recover some vision, and in a letter he wrote to me some months ago he expressed the intention of revisiting London to see his "many good friends." Alas, that was not to be, and the world is poorer for his loss. He never married, and when he was "at home," which was seldom, he lived with his sister in Connecticut.

Medico-Legal

MUNCHAUSEN SYNDROME

[FROM OUR LEGAL CORRESPONDENT]

On July 1 John Sherratt, aged 32, pleaded guilty at Melton Mowbray to obtaining food and drugs valued at £2 from Melton Mowbray War Memorial Hospital, and asked for no fewer than nine similar offences in hospitals in the preceding six months to be taken into consideration. He had been admitted complaining of abdominal pains, and the hospital food and drugs he had had over all 10 efforts amounted to £57 11s. 10d. He was sentenced to six months' imprisonment (*Manchester Guardian*, July 2). Another example of the Munchausen syndrome is reported in our correspondence columns this week (p. 690), but in that case the patient agreed to enter a mental hospital for treatment.

Vital Statistics

Venereal Diseases

In England and Wales during the quarter ending March 31, 1958, 1,088 new cases of syphilis were reported as attending the clinics as compared with 1,292 the previous year. Of these, 171 were classified as primary, secondary, or latent in the first year of infection. 8 cases of congenital syphilis in children aged under 1 year were reported, and 107 cases in persons over that age. New cases of gonorrhoea (with corresponding 1957 figures in parentheses) numbered 6,056 (5,073), of chancroid 76 (77), and of non-gonococcal urethritis (males only) 3,642 (3,662).—*Monthly Bulletin of the Ministry of Health*, August, 1958.

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in July was 105, compared with 116 in the previous month and 114 in July, 1957.

The numbers of cases of industrial diseases in the United Kingdom reported during July, 1958, were as follows: lead poisoning 2, aniline poisoning 1, compressed-air illness 1, epitheliomatous ulceration 10, chrome ulceration 17; total August, 1958.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the years 1949-57 are shown thus -----, the figures for 1958 thus ———. Except for the curves showing notifications in 1958, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Week Ending August 30

The largest increases in the numbers of notifications of infectious diseases in England and Wales during the week ending August 30 were 171 for food-poisoning, from 226 to 397, and 40 for whooping-cough, from 770 to 810; the largest decreases were 986 for measles, from 3,796 to 2,810, and 40 for scarlet fever, from 326 to 286.

The largest decreases in the incidence of measles were 146 in Kent, from 270 to 124, 67 in Gloucestershire, from 147 to 80, 56 in Wiltshire, from 85 to 29, 54 in Essex, from 194 to 140, 54 in Lancashire, from 465 to 411, and 53 in Surrey, from 103 to 50. Only small variations were reported in the local returns of scarlet fever. The largest fluctuations in the trends of whooping-cough were a rise of 35 in Warwickshire, from 35 to 70, and a fall of 39 in Sussex, from 70 to 31. No case of diphtheria was notified; in the preceding week there were 2 notifications.

The notifications of acute poliomyelitis numbered 78, and these were 4 more for paralytic and 3 fewer for non-paralytic cases than in the preceding week. The largest returns were Lancashire 15 (Manchester C.B. 6, Burnley C.B. 2, Preston C.B. 2, Nelson M.B. 2), Yorkshire West Riding 9 (Leeds C.B. 3, Sheffield C.B. 2), Devonshire 5 (Plymouth C.B. 3), Staffordshire 5 (Stoke-on-Trent C.B. 2).

The notifications of dysentery numbered 376 and were 8 fewer than in the preceding week. The chief centres were Yorkshire West Riding 69 (Leeds C.B. 28, Thorne R.D. 15), Lancashire 67 (Liverpool C.B. 15), London 41 (Islington 11), and Warwickshire 31 (Birmingham C.B. 19).

One-half of the notifications of food-poisoning were from Hampshire (Basingstoke R.D. 153, Winchester M.B. 37).

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending August 23 (No. 34) and corresponding week 1957.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the whole of England and Wales (London included). London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenza pneumonia.
§ Includes puerperal pyrexia.

Medical News

Medical Research Council.—The Committee of Privy Council for Medical Research, after consultation with the Medical Research Council and with the president of the Royal Society, have appointed as members of the M.R.C. Professor R. H. S. THOMPSON, professor of chemical pathology at Guy's Hospital Medical School; Professor E. J. WAYNE, regius professor of practice of medicine at Glasgow; and Professor B. W. WINDEYER, professor of radiology at the Middlesex Hospital.

Imperial Cancer Research Fund.—Dr. J. CRAIGIE, F.R.S., has resigned his post as director of the Fund's Mill Hill laboratories, so that he can devote himself entirely to research. Dr. R. J. C. HARRIS is joining the Fund's scientific staff on October 1 to take up a new appointment as head of the division of experimental biology and virology. He will also be responsible, under the director, Professor G. F. MARRIAN, F.R.S., for the general administration of the Mill Hill laboratories. Dr. A. R. CURRIE, at present assistant pathologist at the Royal Infirmary, Glasgow, has been appointed head of the division of pathology, and will take up his duties on October 1, 1959.

Polio Vaccination.—On July 21 Mr. DEREK WALKER-SMITH announced the Government's intention of extending their poliomyelitis vaccination programme by raising the upper age limit from 15 to 25, including a wider range of hospital staff, and making a start on third injections (*Journal*, July 26, pp. 218 and 254). Administrative details of these extensions have now been sent to local health authorities, hospital authorities, and executive councils. The Ministry recommends first, however, a drive to complete the vaccination of existing priority groups—children between the ages of 6 months and 15 years, expectant mothers, general practitioners, and certain hospital staff and their families. Raising the age limit to 25 is estimated to make a further 6,250,000 persons in Britain eligible for vaccination; the extension to further hospital staff (including medical students) and families will account for another 500,000 persons; and those due for third injections will comprise about 200,000 vaccinated in 1956 and 3,500,000 vaccinated in 1957. These extensions are based on advice given by the joint committee on poliomyelitis vaccine under Lord COHEN OF BIRKENHEAD's chairmanship, set up by the Central and Scottish Health Services Councils. By the end of last month a total of 16,164,995 doses of vaccine had been distributed in Britain, of which 5,680,871 were British and 10,484,117 Salk vaccine.

Committee on Artificial Insemination.—The membership of the Home Secretary's committee of inquiry into the practice and legal consequences of human artificial insemination (*Journal*, August 9, p. 397) has now been announced. There are three members of the medical profession, Dr. PRISCILLA FITZGIBBON, an anaesthetist and also magistrate to a juvenile court; Dr. D. T. McDONALD, a general practitioner and former president of the North of England Branch of the B.M.A.; and Professor R. E. TUNBRIDGE, professor of medicine at Leeds University. The other members are Mrs. PEGGY JAY, Mr. R. RISK, a former president of the Law Society of Scotland, Mr. J. ROSS, formerly head of the children's department at the Home Office, Mr. JUSTICE STEVENSON, a judge of the Probate, Divorce, and Admiralty Division, and Mrs. ELIZABETH WHITLEY. The committee's chairman, as announced earlier, is Lord FEVERSHAM. The secretary is Mr. R. F. D. SHUFFREY, of the Home Office (Whitehall, London, S.W.1), to whom any correspondence should be addressed.

Society for the Study of Fertility.—The officers and committee for 1958-9 are as follows: chairman, Dr. T. MANN, F.R.S.; secretary, Dr. A. S. PARKES, F.R.S.; editorial secretary, Professor R. S. HARRISON; treasurer, Mr. H. H. FOURACRE BARNES; ordinary members of the committee, Dr.

G. I. M. SWYER, Dr. P. M. F. BISHOP, Dr. E. J. C. POLGE, Miss P. SCOTT, and Mr. H. G. HANLEY. The Society's annual conference will be held next year in Dublin from May 28 to 30.

Hon. Fellows of Royal Faculty.—At a ceremony at the Royal Faculty of Physicians and Surgeons of Glasgow on August 29 the president, Professor STANLEY ALSTEAD, conferred honorary fellowships on Sir ALEXANDER FLECK, F.R.S., president of the British Association and chairman of Imperial Chemical Industries; Sir MAURICE BLOCH, founder of the Maurice Bloch Trust and donor of the Maurice Bloch lecture theatre; Professor CARL H. BROWNING, F.R.S., emeritus professor of bacteriology at Glasgow University; and the Hon. Mrs. STIRLING OF KEIR for her lifetime's work on behalf of the medical and medical auxiliary services. In the 359 years of its existence the Royal Faculty has conferred its honorary fellowship on only 56 previous occasions, and only once before on a lady.

F.R.F.P.S.—The following were admitted fellows of the Royal Faculty of Physicians and Surgeons of Glasgow on September 1: *Qua* physicians, Dr. S. MUKHERJEE, Professor T. FERGUSON RODGER, Dr. G. RUTLEDGE, and Professor T. SYMINGTON; *qua* surgeon, Mr. R. RANCHODBHAI PATEL.

Medical Chairs in Nigeria.—Mr. W. W. DAVEY, consultant surgeon to the Whittington Hospital, London, has been appointed to the chair of surgery at University College, Ibadan, in succession to Miss BEATRICE JOLY. Mr. Davey is a graduate of Queen's University, Belfast. Dr. G. M. EDINGTON, consultant pathologist to Whiston and Rainhill Hospitals, Liverpool Region, and formerly specialist pathologist in charge of the Medical Research Institute and Laboratory Services, Gold Coast, has been appointed to the chair of pathology at Ibadan in succession to Dr. B. G. T. ELMES. Dr. Edington graduated from Glasgow University.

Nigerian Minister in London.—The Nigerian Federal Minister of Health, Mr. AYO ROSILI, arrived in London last week for discussions here and on the Continent with mental health experts.

Health of Directors.—The Institute of Directors has set up a medical research unit to inquire into the health problems of directors. Mr. H. B. WRIGHT, F.R.C.S., formerly surgical officer to the Shell Petroleum Company, is in charge of the unit. The institute defines the unit's purpose as of the unit. The institute defines the unit's purpose as follows: (1) To demonstrate statistically the facts about the special occupational health hazards to which executives are liable; (2) to define and isolate the causes and effects of such hazards; and (3) to find ways of overcoming them.

Fellowship for Cancer Research.—Applications are invited for a fellowship tenable at the Memorial Center, New York, a training centre specializing in cancer and allied diseases and affiliated to Cornell University Medical College. The fellowship (salary \$6,000) is for one year, normally beginning July 1, and is renewable for one or two years. Candidates must be graduates of medical schools approved by the American Medical Association and have completed at least two years' postgraduate training in internal medicine in addition to a year's internship. The fellowship provides the opportunity for study and clinical investigation at the Memorial Center. Further information is obtainable from Dr. LLOYD F. CRAVER, Memorial Center for Cancer and Allied Diseases, 444, East 68th Street, New York, 21.

Medical Section of S.F.A.—The Scientific Film Association has established a medical section. Further information about the new section may be obtained from the secretary, S.F.A., 3, Belgrave Square, London, S.W.1.

"Family Doctor."—The theme of the September issue of *Family Doctor* is "back to school." Subjects such as growing boys and girls, immunization, and intelligence are reviewed.

COMING EVENTS

Royal College of Surgeons.—The College's second provincial meeting of fellows and members is being held at Cardiff on September 26 and 27. The programme includes a dinner, a scientific session at the Cardiff Royal Infirmary, the annual meeting of the College, and a lecture by Sir RUSSELL BRAIN on "The Cervical Spine." Further information may be obtained from the secretary, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2.

Green-Armytage Anglo-American Sterility Lecture.—Mr. V. B. GREEN-ARMYTAGE will lecture on September 26 at 5 p.m. at the Royal Society of Medicine. His subject will be "Recent Advances in the Surgery of Infertility."

National Society for Clean Air.—Annual conference and exhibition, October 1-3 in Llandudno. Details from the society, Palace Chambers, Bridge Street, London, S.W.1.

Sheffield Medical School.—Old Students' Association dinner, October 11, 6.30 p.m. for 7 p.m. at Firth Hall. Details from the secretary of the association, c/o Department of Pathology, University of Sheffield, Sheffield, 10.

NEW ISSUES

SPECIALIST JOURNALS AND ABSTRACTS

The journals listed below are obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Journal of Neurology, Neurosurgery and Psychiatry.—Issued quarterly (£3 annually). The new issue (Vol. 21, No. 3), includes: CEREBELLAR HYPOPLASIA ASSOCIATED WITH SYSTEMIC DEGENERATION IN EARLY LIFE. R. M. Norman and H. Ulrich. CLINICAL AND ELECTROENCEPHALOGRAPHIC OBSERVATIONS IN ALZHEIMER'S DISEASE. F. Letemendia and G. Pampiglione. INVESTIGATIONS OF E.E.G. FINDINGS IN PRESENILE DEMENTIA. D. W. Liddell. THE CENTRIFUGAL PATHWAY FOR MICTURITION WITHIN THE SPINAL CORD. P. W. Nathan and Marion C. Smith. LANGUAGE DISORDER IN A CASE OF KORSAKOFF'S SYNDROME. P. R. F. Clarke. Maria Wyke and O. L. Zangwill. THE SURGICAL SEPARATION OF SIAMESE TWINS CONJOINED BY THE HEADS (CEPHALOPAGUS FRONTALIS) FOLLOWED BY NORMAL DEVELOPMENT. Maitland Baldwin and Anatole Dekaban. YAWNING. Jacques Barbizet. OPHTHALMIC HERPES ZOSTER WITH CONTRALATERAL HEMIPLEGIA. C. Anastasopoulos, K. Routsonis, and C. S. Ierodiakonou. A PRELIMINARY REPORT ON THE LACK OF TOXICITY OF A PREPARATION OF TOTAL RAUWOLFIA ALKALOIDS. Homai M. Colabawalla. THE SYNDROME OF ACUTE CENTRAL CERVICAL SPINAL CORD INJURY. Richard C. Schneider, John M. Thompson, and Jose Bebin.

Abstracts of World Medicine.—Issued in the first week of each month, this journal contains abstracts of important papers selected from the current medical literature of the world. Annual subscription £4 4s.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Friday, September 19

BRITISH TUBERCULOSIS ASSOCIATION.—At 26, Portland Place, W., 5 p.m., Dr. D. A. Mitchison: Methods of Assessment and the Significance of Drug Resistant Mycobacterium Tuberculosis; Dr. D. B. Llewellyn-Morgan: Some Factors in the Production of Drug Resistant Mycobacterium Tuberculosis; Dr. H. E. Thomas: Clinical Findings in Birmingham Patients with Drug Resistant Organisms; Dr. Sheila M. Stewart: Correlation Between the Clinical Outcome of Treatment and the Results of Bacteriological Resistance Tests. Discussion to be opened by Dr. J. G. Scadding.

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. J. L. Livingstone: clinical demonstration.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Davidson.—On July 2, 1958, at 18, Frank Dixon Way, Dulwich, London, S.E., to Veronica (formerly Fortune) and John H. Davidson, M.B., B.S., a brother for Diana and Penelope—Michael Peter John.

Hughes.—On August 31, 1958, at Aberystwyth, to Dr. Elinor (formerly Cleland) and Dr. John H. Hughes, a daughter—Kathryn Anne.

DEATHS

Frazer.—On September 8, 1958, at the Royal Southern Hospital, Liverpool, William Mowll Frazer, O.B.E., M.D., M.Sc., D.P.H., aged 70.

Hance.—On September 5, 1958, at Machynlleth, Montgomeryshire, Sir James Bennett Hance, K.C.M.G., K.C.I.E., O.B.E., M.D., F.R.C.S.Ed., Lieutenant-General, I.M.S., retired, aged 71.

Oakley.—On August 16, 1958, Philip Douglas Oakley, C.B.E., M.R.C.S., L.R.C.P., D.T.M., late D.M.S., Sierra Leone, of Coasters Cottage, Roundabout, Pulborough, Sussex.

Wells.—On August 13, 1958, at 10, Lambridge, Bath, Somerset, Lionel Thomas Wells, M.R.C.S., L.R.C.P., aged 88.

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Immediate Treatment of Cardiac Infarction

Q.—What immediate emergency treatment should be given at the onset of a case of cardiac infarction with syncope?

A.—Syncope at the onset of cardiac infarction is relatively uncommon. It is usually of the vaso-vagal type and hence short-lived and self-limiting. The patient should be laid flat and morphine given to relieve pain. Rarely it may be due to heart block (Stokes-Adams attack), when one would be forced to use isoprenaline, 5 mg. rectally, in spite of its stimulant action on the myocardium with consequent tendency to cause ventricular fibrillation. If shock, as distinct from syncope, is present, with a systolic blood pressure of 80 mm. Hg or below, then an attempt should be made to elevate the pressure with mephentermine sulphate, 15 mg. intramuscularly, repeated as necessary, in addition to complete rest, oxygen, and pain relief. Recently digoxin has been suggested as a vasopressor, and, while undoubtedly useful, it may cause sudden death from ventricular fibrillation and hence cannot be unreservedly recommended.

Pregnancy after Nephrectomy

Q.—Does the risk of renal damage justify advising against pregnancy in a woman of 25 who has recently had a nephrectomy for complete fibrosis of the left kidney?

A.—Before advising this patient about future pregnancy the function of the remaining kidney must be fully assessed. There have been many cases recorded of successful pregnancy following nephrectomy when the remaining kidney was healthy. This undergoes compensatory hypertrophy, and two years should be allowed to elapse between the operation and the beginning of a pregnancy. If the nephrectomy was for renal tuberculosis the prognosis is not so good. The management of pregnancy after nephrectomy does not differ from normal except there must be extra vigilance in the early detection and prevention of pre-eclamptic toxæmia. Pyelonephritis must be treated promptly, and, if this is resistant to treatment, the pregnancy should be terminated.

Midwifery Bag

Q.—What should the midwifery bag of a general practitioner contain?

A.—**Instruments.**—Most general practitioners try to equip their bags with all the instruments they will need in midwifery: sterilizer; scissors; needles; obstetric forceps; artery forceps; needle holder; vaginal speculum; dressing forceps; sterile catgut and silk worm or nylon; syringes—1 ml. and 10 ml. with suitable needles; rubber catheter—fine; packet of cord thread—sterilized. I also carry long artery forceps, ovum and volsellum forceps, and a Drew Smythe catheter. I include in a small canvas instrument-bag two intravenous cannulas and a scalpel. **Apparel.**—Rubber gloves—two pairs or more—and a tin of glove powder; face masks; one apron. **Drugs.**—Morphine, pethidine, "omnupon," and scopolamine in ampoules; oxytocin and ergometrine in ampoules; hyaluronidase ampoules; sedative tablets—e.g., tab. butobarbiton., gr. 1½ (0.1 g.); tab. codein. co. **Anaesthetics.**—Some doctors carry both local and general anaesthetics (if they use chloroform) in the midwifery bag. Others, who use more complicated forms of anaesthesia, require more bags. I suggest one

bottle of chloroform and drop bottle; procaine 2% in a 10-ml. rubber-capped bottle (for use in suturing perineums); sodium thiopentone and sterile water in ampoules (which I would use only for control of eclamptic fits); Schimmelbusch mask; lint; gag and tongue forceps; strap or harness for lithotomy position. Gas (N₂O) and air or trichlorethylene have to be carried separately. If a Minnitt machine is used it is possible to replace one N₂O cylinder with an oxygen cylinder for giving oxygen to mother or child. **Antiseptics.**—Scrubbing brush; cake of soap; "dettol," small bottle or equivalent; small kidney bowl.

A douche can is hardly ever used now, but the rubber tubing may be useful for making veins stand out. It is essential to have another bag containing transfusion-giving sets, bottles of serum or dextran, and sterile water. This bag may also hold 1 lb. (0.45 kg.) of cotton-wool. Finally, a word of warning—never carry a narcotic drug like morphine in a bottle which looks or feels like a bottle of local anaesthetic. No doubt general practitioners always read the label, but too often the eye sees what it expects to see rather than what is on the label.

Seaweed Preparations

Q.—Is there any poisonous principle in *Fucus* or other seaweed? Were the slimming properties attributed to these plants real or imaginary?

A.—There are no poisonous principles in medical preparations made from seaweed. They have no positive slimming properties, but they have practically no calorie value and act to some extent as bulk purgatives in the same way as methyl cellulose or agar-agar. Foods made with methyl cellulose, such as biscuits, have a certain satiety value, while agar-agar, which is actually made from seaweed, when sprinkled on food has hygroscopic qualities and consequently has a laxative effect owing to the bulk which it induces in the diet. In consequence, they may be said to exercise a secondary effect in causing slimming.

Correction.—Dr. A. J. Dalzell-Ward informs us that he made an inadvertent omission from his letter on prevention of lung cancer (*Journal*, August 30, p. 563). The first sentence of the last paragraph should have read "... the mortality from lung cancer amongst smokers was three times that amongst men who had given up the habit more than 10 years previously, and 76% greater than that amongst men who had given up the habit less than 10 years previously."

Collected Articles from the "British Medical Journal"

The following books are available through booksellers or from the Publishing Manager, B.M.A. House. Prices, which include postage, are now the same for both inland and overseas.

Emergencies in General Practice (26s. 9d.).

Refresher Course for General Practitioners, Volumes 2 and 3 (26s. 9d.).

Clinical Pathology in General Practice (22s. 3d.).

Any Questions?, Volumes 2 and 3 (8s. 3d. each).

THE EISENMENGER SYNDROME

OR PULMONARY HYPERTENSION WITH REVERSED CENTRAL SHUNT*

BY

PAUL WOOD, O.B.E., M.D., F.R.C.P.

Director, Institute of Cardiology; Physician, National Heart Hospital; Physician-in-Charge, Cardiac Department, Brompton Hospital, London

[WITH SPECIAL PLATE]

Nomenclature

Eponymous titles are no longer in fashion, because they frequently lend themselves to controversy over historical precedence, invite criticism on the grounds of descriptive inaccuracy, and can usually be replaced with advantage by a scientific name which simultaneously identifies, defines, and classifies the disease in question. The term "Eisenmenger's syndrome," as used in these lectures, therefore requires some explanation, especially since the Editor of the *British Heart Journal* stated recently that it has "outlived [its] usefulness and should no longer be used in clinical medicine" (Brotmacher and Campbell, 1958).

An eponymous title may be justified, however, when it has been introduced by someone singularly entitled to do so (Abbott and Dawson, 1924), when it has become familiar by customary use on an international scale over a period of 34 years, when the aetiology and precise mechanism of the syndrome are still controversial, and when there is no convenient alternative title likely to stand the test of time. Nothing is gained by changing customary nomenclature prematurely. To dispense with the term altogether, and to regard the Eisenmenger complex simply as a variety of ventricular septal defect, is to deny the very essence of the syndrome, for, as will become clear later, its distinguishing feature lies not in the anatomy of the defect, but in the behaviour of the pulmonary circulation.

It may help at this early stage to state precisely what Eisenmenger described.

Dr. Victor Eisenmenger published his paper on "congenital defects of the ventricular septum" in 1897. He described in detail a typical example of the condition that has since become known as Eisenmenger's complex. His patient was a powerfully built man of 32 who gave a history of cyanosis and moderate breathlessness since infancy. The cyanosis increased considerably on effort. He managed well enough, however, and was able to lead an active life until January, 1894, when dyspnoea increased and oedema set in. Seven months later (August) he was admitted to hospital in a state of heart failure.

Examination revealed marked cyanosis, clubbing of the fingers and toes, thickening of the distal joints, and

*The Croonian Lectures delivered before the Royal College of Physicians of London on May 13, 1958.

polycythaemia. The venous pressure was raised, the liver distended, and oedema extensive. The right side of the heart was obviously enlarged, and there was a loud systolic murmur, accompanied by a thrill, maximal in the third and fourth left intercostal spaces near the sternal edge. The murmur was not conducted at all well to either the aortic or the pulmonary areas, and would have been regarded as tricuspid had it not been for the lack of a giant v wave in the jugular pulse. The pulmonary second sound was not impressive, but a basal diastolic murmur, presumably from pulmonary incompetence, developed later. He improved with rest and digitalis, but collapsed and died more or less suddenly on November 13 following a large haemoptysis.

The clinical diagnosis of ventricular septal defect was based on the systolic murmur and thrill in the third and fourth left interspaces. The haemoptysis was attributed to pulmonary infarction.

Both were confirmed at necropsy. The defect was round and situated in the membranous septum; it measured 2 to 2.5 cm. in diameter, and was placed in such a way that the lumen of the aortic orifice fell half over the left ventricular outflow tract and half over the right. Both aortic and pulmonary valves appeared to be competent. The left ventricle measured 8 to 10 mm. in thickness, the right 10 mm. The latter was much dilated and obviously the bigger chamber. The tricuspid ring was very widely stretched. There was considerable atherosclerosis of the pulmonary artery and its branches, but none in the aorta. In the left upper and right lower lobes of the lungs there was extensive haemorrhagic infarction secondary to multiple thrombosis.

Eisenmenger interpreted the situation as follows: in ventricular septal defect (he wrote) the difference in pressure between the left and right ventricles ensured a left-to-right shunt; the pulmonary circulation was therefore overfilled, the systemic circulation underfilled; increased stiffness of the lungs hindered ventilation and congestion hampered gaseous exchange; cyanosis depended more, however, on the poor systemic circulation—that is, it was peripheral rather than central. He discussed the "riding aorta" at considerable length and concluded that this was caused neither by a congenital fault of rotation nor by the direction of blood flow through the defect, but that it was a more or less

5098

inevitable consequence of the position of the defect itself in relation to the normal anatomy of the parts concerned, and was more apparent than real. Eisenmenger was unaware that the shunt was reversed in the case he described so carefully, despite his statement that a rise in pulmonary vascular resistance—from multiple thrombosis, for example—would equilibrate the pressures in the two circulations and so prevent both shunt and murmur.

His misinterpretation was based chiefly on two observations: first, since the cyanosis had been present from birth, he could not attribute it to reversed shunt from thrombo-obstructive pulmonary hypertension, for the thromboses were terminal; second, the absence of a giant v wave in the jugular pulse forced him to ascribe the systolic murmur and thrill to a left-to-right shunt through the defect rather than to tricuspid incompetence. He had no means of knowing that a high pulmonary vascular resistance might exist from birth independent of thrombo-obstructive lesions, and he was obviously unaware of the character of the venous pulse in cases of tricuspid incompetence with normal rhythm. In his honour, however, may be enumerated the following: (1) The case history that he described was complete, faultless, and wholly typical. (2) He stated that in otherwise uncomplicated ventricular septal defect pulmonary hypertension resulting from obstruction in the pulmonary circulation would abolish both left-to-right shunt and the classical murmur. (3) He took great pains to prove that an overriding aorta played no part in the physiological disturbance of the circulation.

Conflicting Hypotheses

Abbott and Dawson (1924) attributed the cyanosis of Eisenmenger's case to a right-to-left shunt through the defect on account of the overriding aorta, and Abbott described in detail a similar case herself (Baumgartner and Abbott, 1929). In her well-known table, which has recently been reproduced (Abbott, 1952), she analyses seven such cases. She ascribed the systolic murmur to the inter-ventricular shunt.

Taussig (1947) stated that "the essential feature of the Eisenmenger complex is that the aorta is dextroposed and overrides the right ventricle." That she was dissatisfied with this explanation, however, is clear from several other statements that she made: namely, "The dynamics of the circulation may be such that the powerful ejection of blood from the left ventricle into the aorta draws by suction a larger volume of blood from the right ventricle into the aorta than would be shunted through the opening if the force of ejection were the same in the two ventricles" (cf. the common ejectile force from both ventricles invoked by Edwards, 1957); and, "The cause of the cyanosis in these patients is by no means clear. In such individuals there may well be some alteration in the pulmonary epithelium or in the pulmonary vascular bed which prevents complete oxygenation of the blood in its passage through the lungs" (Taussig and Blalock, 1947). At that time she believed that "cyanosis was usually absent in infancy and early childhood," and may have been unable to correlate this with the override hypothesis.

Brown (1950) considered that the essential features of the Eisenmenger complex consisted of "a high defect of the interventricular septum, dextroposition of the aorta, and a normal or dilated pulmonary artery." He stated that the cyanosis was due partly to a right-to-left shunt depending on the degree of override, and partly to "failure of adequate oxygenation in the lungs."

Thus 50 years of cardiology failed to advance Eisenmenger's description, and opinion remained opposed to his belief that the overriding aorta was irrelevant. It was not

until 1947 that anyone followed up his suggestion that obstruction in the pulmonary vascular bed would be expected to raise the pulmonary blood pressure and to abolish both the left-to-right shunt and the murmur of uncomplicated ventricular septal defect. This was when Bing *et al.* (1947) demonstrated pulmonary hypertension at systemic level with bidirectional shunt in five cases of Eisenmenger's complex.

Since then innumerable studies have confirmed that pulmonary hypertension at systemic level is invariable in Eisenmenger's complex, typical earlier papers being those of Burchell *et al.* (1950), Wood (1950, 1952), Selzer and Laqueur (1951), and Soulié *et al.* (1953). The part played by pulmonary hypertension may be summed up in Selzer's words "that the most characteristic feature of Eisenmenger's complex is the presence of severe pulmonary hypertension."

As a result of such studies the concept quickly grew up that Eisenmenger's complex is pulmonary hypertension with reversed or bidirectional shunt through a large ventricular septal defect. Anatomical overriding or dextroposition of the root of the aorta may or may not be found at necropsy in clinically indistinguishable cases.

This has not ended the controversy, however, but has merely shifted the grounds of differing opinion. The debate now centres in the nature of the high pulmonary vascular resistance. Does this result from persistence of the foetal type of pulmonary circulation (Civin and Edwards, 1950), independent coincidental congenital disease of the pulmonary circulation (Evans, 1951; Kohout *et al.*, 1955), degenerative or thrombo-obstructive pulmonary vascular disease secondary to high flow or hyperkinetic pulmonary hypertension (Whitaker, 1958; Brotmacher and Campbell, 1958), transmission of a high left ventricular pressure to the pulmonary circulation owing to lack of obstruction at the site of a large defect (Edwards, 1957; Brotmacher and Campbell, 1958), a high right ventricular pressure initially determined by the override so that the right ventricle has to help support the systemic blood pressure (Soulié *et al.*, 1953), or initially from reactive pulmonary vasoconstriction, degenerative and late thrombo-obstructive pulmonary vascular disease being secondary (Wood, 1952, 1956, 1958)? With so many conflicting hypotheses concerning the origin and maintenance of this pulmonary hypertension at the present time, it would be begging the question to introduce new aetiological nomenclature.

Definition

But Eisenmenger's complex may be redefined with great advantage. Almost all writers have defined it as a cyanotic form of congenital heart disease with a large ventricular septal defect and overriding of the aorta, and in recent years pulmonary hypertension has been added. In the light of present knowledge, however, and fitting better with Eisenmenger's description, ideas, and insistence on the artificiality of the override, a better definition would be *pulmonary hypertension at systemic level, due to a high pulmonary vascular resistance (over 800 dynes sec./cm.²), with reversed or bidirectional shunt through a large ventricular septal defect (1.5 to 3 cm. across)*. Rarely the systemic and pulmonary vascular resistances may be so delicately balanced as to permit of no material shunt in either direction. To have no definitive name by which to call such cases would be intolerable; nor would ventricular septal defect with pulmonary hypertension suffice, for many such cases are not in the same category at all, the pulmonary hypertension being mainly hyperkinetic (due to a high pulmonary blood flow). The definition of Eisenmenger's complex given above is far too cumbersome to use routinely, and so there is little choice but to continue to employ the eponymous term itself, at least for the time being.

Now this modern definition of Eisenmenger's complex leads on to another very important consideration. The syndrome described is essentially pulmonary hypertension with reversed or bidirectional shunt, and it *matters very little*

where the shunt happens to be. At the bedside it is usually easy enough to diagnose the essential physiological situation, but often extremely difficult, if not impossible, to identify the site of the defect; indeed, to do so with certainty may still prove very difficult after full physiological investigation, including cardiac catheterization, angiocardiology, dye dilution curves, and other special tests. The frequency with which necropsies disclose an anatomical diagnosis different from what was expected is as embarrassing as it is educational. The fact is that a remarkably similar physiological situation occurs when any large communication between the two circulations is complicated by a pulmonary vascular resistance around systemic level. There are no fewer than 12 different anatomical abnormalities which may present in this way (Table I), and, in view of the frequent uncertainty

TABLE I.—Causes and Frequency of Eisenmenger's Syndrome

	Total No. of Cases	No. with Eisenmenger Reaction	Frequency of Eisenmenger Reaction (%)
i. Patent ductus arteriosus	180	29	16
ii. Aorto-pulmonary septal defect	10	6	60
iii. Persistent truncus arteriosus	4	4	100
iv. Transposition of the great vessels (with V.S.D.)	12	7	58
v. Corrected transposition (with V.S.D.)	3	3	100
vi. Single ventricle	6	6	100

regarding the exact anatomical diagnosis, a term which embraces them all is highly desirable. Since Eisenmenger's case, when seen clinically at that time, was no more likely to have had a ventricular septal defect than any of the other 11 conditions tabulated, with the possible exception of a simple atrial septal defect, I suggested extending the meaning of the expression "Eisenmenger's syndrome" to embrace these 12 conditions when behaving physiologically like "Eisenmenger's complex" proper (Wood, 1956).

In these lectures I propose to elaborate this theme, to discuss in detail the differential diagnosis between the various members of the group both at the bedside and by various means of special investigations, to probe the mechanism responsible for the high pulmonary vascular resistance, and finally, in synthesis, to offer a hypothesis which may explain both the common physiological behaviour and the exceptions to it.

Material

The analysis is based on a consecutive series of 127 cases of Eisenmenger's syndrome (as just defined) studied personally over a period of 11 years. Nearly all were catheterized, angiocardiology was carried out when considered necessary, and during the last year dye dilution curves have also been recorded. Eighteen of these 127 patients died, and a necropsy was obtained in 15 of them. The clinical diagnosis of the anatomical defect was correct in four, wrong in two, in nine, half correct but incomplete in four, wrong in two, and unproved because there was no necropsy in the other three. This represents a completely accurate clinical diagnosis in only 60%, or a rate of error far in excess of that experienced with any other form of congenital heart disease, and emphasizes the need for a single term to embrace the whole group clinically. Of the total of 127 cases, 22 have been rejected on the grounds of too much uncertainty with regard to the site of the defect.

In addition, and owing to the kindness of many friends in Britain, I have been able to collect details of a further 38 cases which were well worked out during life and which

subsequently came to necropsy. In these the shunt was aorto-pulmonary in 16, interventricular in 11, and inter-atrial in 11. To avoid duplication—for no doubt many of these cases have been or will be reported elsewhere—I am not including them in the analysis, but merely using them as a means of checking the accuracy of other data, and to facilitate the interpretation of my own findings. Without such necropsy control too many errors of interpretation are likely to be perpetuated. When data from these 38 post-mortem cases is used in this paper the fact is stated.

My own material is presented in Table I and represents 17.5% of a total of 727 cases of congenital heart disease with a communication of some sort between the systemic and pulmonary circulations. The frequency of the Eisenmenger reaction in each type of defect is given in the third column. It simplifies matters considerably if cases are regarded as having a shunt at aorto-pulmonary, ventricular, or atrial level, without stating specifically the nature of the defect. For example, both patent ductus and aorto-pulmonary septal defects have an aorto-pulmonary shunt, although there are specific differences between the two; again, persistent truncus, transposition or corrected transposition with ventricular septal defect, ventricular septal defect itself, single ventricle, and persistent ostium primum all shunt to an important degree at ventricular level, and in this respect may be taken together; similarly, atrial septal defect, single atrium, hemianomalous pulmonary venous drainage, and total anomalous pulmonary venous drainage directly or indirectly into the right atrium form a third group, all having the shunt at atrial level.

Frequency of the Eisenmenger Reaction

Eisenmenger's syndrome, as defined in this paper, accounted for 8% of the first 1,000 cases of congenital heart disease in my series.

Since necropsies prove conclusively that the Eisenmenger reaction is excited only by large communications between the two circulations, the frequency of such reactions in relation to the site of the communication should be assessed only as a percentage of large defects. In the 53 cases of Eisenmenger's syndrome that came to necropsy, the minimal size of aorto-pulmonary, ventricular, and atrial communications was 0.7 cm., 1.5 cm., and 3 cm. respectively. In the absence of the Eisenmenger reaction, defects of this order result in pulmonary blood flows ranging between 15 and 30 litres per minute, or pulmonary/systemic flow ratios of 3.5 to 6, at least in respect of aorto-pulmonary and ventricular communications; atrial septal defects are probably all large enough to excite the Eisenmenger reaction, but only those giving rise to similar pulmonary blood flows have been included in the calculations. The clinical features of these relatively large defects were in harmony with the physiological findings. It is appreciated that these are very artificial criteria for assuming that the defects were as large as those found in the Eisenmenger syndrome, but the object is simply to exclude from the estimates all those cases of mild or moderate severity which are known never to excite the Eisenmenger reaction.

The frequency of the Eisenmenger reaction in relation to large communications between the two circulations is given in Table II. It will be seen that Eisenmenger's syndrome occurs in over half of the cases with aorto-pulmonary or ventricular communications, but in only 9% of those with large atrial septal defects, and it is emphasized that this six-

TABLE II.—Frequency of the Eisenmenger Reaction in Relation to the Site and Size of the Defect

Site of Communication	Total No. of Cases	No. with Large Defects	No. with Eisenmenger Reaction	No. with Eisenmenger Reaction Expressed as percentage of Large Defects
Aorto-pulmonary	190	66	35	53
Interventricular	179	97	50	52
Interatrial	333	214	20	9

fold difference must be a conservative estimate, for it is probable that communications at aorto-pulmonary or ventricular level always excite the Eisenmenger reaction if they are of sufficient size, and that nearly all atrial septal defects are critical in the sense defined.

No explanation of the physiological mechanism underlying the Eisenmenger reaction is tenable unless it explains this remarkable difference.

Age

The average age of uncomplicated cases of patent ductus, ventricular septal defect, and atrial septal defect when first seen was 18, 13, and 26 respectively; when complicated by the Eisenmenger reaction otherwise similar cases had an average age of 19, 22, and 35 respectively.

The great majority of cases of uncomplicated patent ductus and ventricular septal defect (67% and 80% respectively) are referred to specialist clinics in childhood or adolescence. Early recognition of these cases probably depends on their characteristic and impressive murmurs. The bruit de Roger is especially difficult to overlook in view of its central position, and that may be why ventricular septal defect is recognized sooner than patent ductus, for a continuous murmur high up under the left clavicle may not be heard on casual auscultation. That the Eisenmenger group is referred somewhat later may be explained by the absence of these murmurs. Less than 50% of patients with uncomplicated atrial septal defect are referred in childhood or adolescence, no doubt for the same reason; but the much later reference of atrial cases with the Eisenmenger reaction can have no such explanation, and must mean that pulmonary hypertension in atrial septal defects is a late-acquired characteristic. That it is not an inevitable consequence of a high pulmonary blood flow acting on the pulmonary vasculature over a long period of time, however, is shown by the fact that 12% of uncomplicated cases of atrial septal defect and 15% of those with the Eisenmenger reaction were in persons between 50 and 75 years of age. It is clear that 70 years of pulmonary plethora may fail to raise the pulmonary vascular resistance.

Sex

Fig. 1 shows that the sex distribution in patent ductus (M/F=1/2) and ventricular septal defect (M/F=1) is the same in uncomplicated cases and in those with the Eisen-

FIG. 1.—Sex distribution.

menger reaction. This disposes of the idea that Eisenmenger's complex might be ventricular septal defect associated with coincidental primary pulmonary hypertension, for the M/F sex ratio in the latter is 1/4.

In atrial septal defect, however, females are more common in the Eisenmenger group, in which they are as frequent as in primary pulmonary hypertension. This confirms that atrial septal defect complicated by a high pulmonary vascular resistance differs fundamentally from

Eisenmenger's complex, and from patent ductus with reversed shunt. Its late onset has already been offered as evidence that it is acquired, and now its high female bias suggests that it may have some factor in common with primary pulmonary hypertension.

Associated Anomalies

In a consecutive series of 1,250 cases of congenital heart disease certain relationships between anomalies outside the cardiovascular system and particular kinds of cardiovascular malformation have become firmly established. These may be enumerated as follows.

1. When congenital heart disease occurred in more than one member of a family, which it did in 5% of cases, it was nearly always of the same kind. This rule held good for patent ductus, ventricular septal defect, and atrial septal defect, as well as for coarctation, aortic stenosis, Fallot's tetralogy, simple pulmonary stenosis, and familial cardiomegaly.

2. Arachnodactyly was far more often associated with atrial septal defect than with any other anomaly, as endorsed by Reynolds (1950), and occurred in 15% of uncomplicated cases and in 12% of those with pulmonary stenosis and reversed interatrial shunt.

3. Deformities of the limbs were associated with ventricular septal defect in seven out of eight instances. Each of the three with polydactyly had Fallot's tetralogy.

4. Maternal rubella favoured patent ductus, as stated by Wesselhoef (1949). When no history of maternal rubella was obtained, cataract and deafness might have similar significance.

5. Mongols are said to be especially prone to have persistent ostium primum or common atrioventricular canal (Brown, 1950). The latter was proved at necropsy in one of our more difficult cases with the Eisenmenger reaction.

6. Hypertelorism alone, or as part of Turner's syndrome, was recognized in 20% of cases with pulmonary stenosis and reversed interatrial shunt, but in only 1% of cases of Fallot's tetralogy.

In the differential diagnosis of Eisenmenger's syndrome due regard should be paid to these observations.

Clinical Features

Onset.—It was usually possible to establish from the history when the Eisenmenger syndrome was first fully developed. Cases with inadequate data were excluded from the analysis. Table III shows that the Eisenmenger syn-

TABLE III.—Onset of Eisenmenger Syndrome

	Duct. %	V.S.D. %	A.S.D. %
Infancy	79	83	8
Childhood and adolescence	4	15	—
Adult life	17	2	92

drome started in infancy in about 80% of cases of patent ductus and ventricular septal defect, but in only 8% of cases of atrial septal defect; even more remarkable was the fact that it started in adult life in only 2% of cases of ventricular septal defect but in 92% of cases of atrial septal defect. No further proof is needed that a high pulmonary vascular resistance in atrial septal defect is acquired. Conversely, a high pulmonary vascular resistance in the great majority of cases of patent ductus and ventricular septal defect seems to be established at birth, or at the latest in infancy.

Effort Intolerance.—As described elsewhere, four grades of effort intolerance are recognized: slight, moderate, considerable, and gross—or, of course, there may be none. Fig. 2 shows clearly that in the Eisenmenger group patent ductus is by far the best tolerated, nearly half of such cases having only slight breathlessness on effort or none at all. There was little difference between ventricular septal defect and atrial septal defect in respect of effort intolerance; the average grading was 2.5 in both—three-quarters of a grade higher than in patent ductus. The lack of symptoms in patent ductus with reversed shunt is attributed to the relatively normal oxygen tension of blood going to the head

and neck; in most cases only the blood passing down the descending aorta below the junction of the duct is appreciably desaturated. As a corollary this explanation demands that breathlessness in the Eisenmenger syndrome is due to a low arterial oxygen saturation in blood passing through the chemoreceptors of the head and neck.

FIG. 2.—Degree of effort intolerance in the three main groups of Eisenmenger's syndrome.

Special Symptoms.—Apart from breathlessness, the chief symptoms of the Eisenmenger syndrome are angina pectoris, syncope, haemoptysis, and congestive heart failure, in that order of onset. The frequency of each in relation to the site of the shunt is given in Table IV.

TABLE IV.—Symptoms of Eisenmenger Syndrome

	Duct. %	V.S.D. %	A.S.D. %
Angina	20	14	15
Syncope	15	14	10
Haemoptysis	12	33	25
Congestive failure	12	8	10

Haemoptysis

The frequency of haemoptysis is emphasized. Its occurrence in 33% of cases of Eisenmenger's complex contrasts sharply with its 4% incidence in a parallel series of 27 cases of primary pulmonary hypertension; and its occurrence in 25% of cases of atrial septal defect with pulmonary hypertension and reversed shunt contrasts equally sharply with its 3% incidence in 300 cases of uncomplicated atrial septal

FIG. 3. Frequency of haemoptysis in relation to age in Eisenmenger's complex.

defect. It is clear from these figures that haemoptysis is not a complication of pulmonary hypertension *per se*, nor of pulmonary plethora.

In patients with Eisenmenger's complex haemoptysis was never seen before the age of 24, but thereafter it occurred with increasing frequency, to reach the 100% mark by the age of 40 (Fig. 3).

At necropsy the common cause of these haemorrhages is pulmonary infarction from pulmonary artery thrombosis (see Pathology), as in Eisenmenger's case. The factor which encourages such thrombosis in Eisenmenger's syndrome rather than in primary pulmonary hypertension may well be polycythaemia; and the factor which determines its onset relatively late in the course of the disease is probably atherosclerosis.

A large haemoptysis was the immediate cause of death in 29% of 42 fatal cases. As a rule, the patient collapsed and died within a few minutes of the onset of the haemorrhage. The sudden reduction of blood volume and fall in central venous pressure may excite a vasovagal reaction as described by Barcroft *et al.* (1944), and collapse of the peripheral resistance must result in an abrupt and profound fall in arterial oxygen tension as the blood swings away from the lungs.

Cyanosis

Cyanosis, clubbing of the fingers, and polycythaemia were all most florid when the shunt was at ventricular level and least with a patent ductus. Thus no case of Eisenmenger's complex was truly acyanotic even at rest, whereas 60% of cases with patent ductus and reversed shunt were acyanotic in the head and upper extremities. At the other end of the scale 42% of those with ventricular septal defect had considerable or gross cyanosis, compared with only 4% of those with patent ductus.

Clubbing of the fingers was, of course, closely associated with cyanosis: it was absent in 76% of the cases with patent ductus and considerable in only 5%; the respective figures for Eisenmenger's complex were 3% and 36%. With both cyanosis and clubbing cases with interatrial shunt occupied an intermediate position.

Polycythaemia was rather less unevenly distributed, indicating that hypoxia in the lower part of the body provided some stimulus to blood formation.

Differential cyanosis with or without differential clubbing was seen in 50% of cases with reversed shunt through a patent ductus. Not infrequently the left hand was an intermediate colour between the pink right hand and the blue feet.

Squatting was uncommon in all members of the Eisenmenger group, but was relatively more frequent with ventricular septal defect (15%) than with atrial septal defect (5%) or patent ductus (3%).

These five facets of arterial desaturation show that shunt reversal in the Eisenmenger complex is usually greater than in cases with atrial septal defect, and that shunt reversal in patent ductus is usually deflected down the descending aorta.

Pulse and Blood Pressure

The pulse was usually small or normal. It was small about twice as often with atrial septal defect (88%) as with ventricular septal defect (37%) or patent ductus (50%). When full or water-hammer in quality, atrial septal defect was never present except in one case with severe anaemia. Bidirectional aorto-pulmonary shunts otherwise provided the only examples of water-hammer pulses (12%).

The blood pressure was much the same in the three main groups comprising Eisenmenger's syndrome, averaging 117/74 with patent ductus, 116/78 with ventricular septal defect, and 110/72 with atrial septal defect.

Jugular Venous Pressure and Pulse.—Both venous pressure and pulse were commonly normal, but a small dominant a wave measuring about 3 mm. Hg was seen in 20 to 25% of cases of each type. A giant a wave measuring

*Transposition or corrected transposition with ventricular septal defect and a high pulmonary vascular resistance is clinically identical with Eisenmenger's complex. Skiagrams, however, may show the narrow vascular pedicle described by Taussig (1938), when the aorta lies immediately anterior to the pulmonary artery (Fig. H): or a left-sided ascending aorta forming a long slightly convex shadow below the aortic knuckle and overlying the left branch of the pulmonary artery, for which it may well be mistaken—indeed, its true identity may not be revealed until its continuity with the great vessels is demonstrated during cardiac catheterization or by means of angiocardigraphy (Fig. I). Good examples were described by Goodwin *et al.* (1949) and by Astley and Parsons (1952). Corrected transposition may be suggested by partial or complete atrio-ventricular block (Walker *et al.*, 1958).*

Atrial septal defect with reversed shunt secondary to a high pulmonary vascular resistance is unusual in men. Symptoms, especially cyanosis, are rare in infancy and childhood, and commonly do not appear before adult life. A late onset is always strongly in favour of atrial septal defect. It is probable that most of those that do begin in infancy are persistent ostium primums or common atrio-ventricular canals. Of the physical signs, a giant *a* wave and right atrial gallop are very suggestive, and a well-split second sound which does not widen on inspiration is virtually diagnostic. The right ventricle and atrium are usually larger in atrial septal defect than in other members of the Eisenmenger group, particularly in those in which cyanosis began in adult life; this is reflected in both the electrocardiogram and the skiagram. A dense dilated right pulmonary artery is also very suggestive.

Single atrium with pulmonary hypertension is indistinguishable from atrial septal defect as just described; *hemianomalous pulmonary venous drainage* closely resembles atrial septal defect clinically, but splitting of the second heart sound may vary with respiration. No cases with the Eisenmenger reaction were recognized in the present series. *Total anomalous pulmonary venous drainage* into the superior vena cava or inferior vena cava also resembles atrial septal defect clinically, but is easily recognized by the characteristic skiagram; no such distinguishing feature marks total anomalous pulmonary venous drainage into the coronary sinus. Severe pulmonary hypertension is also rare in these cases.

Physiological Findings

As defined in the introduction, the Eisenmenger syndrome is pulmonary hypertension at or around systemic level due to a high pulmonary vascular resistance (over 10 units) associated with reversed or bidirectional shunt through a large communication between the systemic and pulmonary circulations at aorto-pulmonary, ventricular, or atrial level: occasionally the physiology of the two circulations is so precisely balanced that there is no shunt in either direction. Each member of the group, however, tends to have its own distinctive characteristics.

TABLE V.—Eisenmenger Syndrome. Physiological Data

General Characteristics of the Eisenmenger Syndrome (Table V)

1. The catheter passed through the defect in 90% of the ducts, one-third of the aorto-pulmonary windows, 28% of ventricular septal defects, and two-thirds of atrial septal defects.
2. A patent foramen ovale was penetrated in four cases of Eisenmenger's complex, but in no case of patent ductus. Left and right atrial pressures were similar and left atrial samples were 90 to 96% saturated with oxygen. In these cases, and also in atrial septal defect with reversed shunt, pulmonary venous samples were fully saturated (95 to 99%). This proves that there is ordinarily no pulmonary factor contributing to the cyanosis of the Eisenmenger syndrome.
3. The pulmonary capillary venous pressure was uniformly normal or low, averaging 2 mm. Hg. and ranging between -1 and 6 mm. Hg. with reference to the sternal angle in all groups. Only in one case with heart failure was it elevated. It is presumably raised, however, in those cases of total anomalous pulmonary venous drainage in which the

FIG. 8.—Identical systolic pressures in the brachial artery, pulmonary artery, and right ventricle in a case of Eisenmenger's complex. Note the normal right atrial pressure pulse.

common vein carrying all the blood from the lungs is stenosed at its junction with the superior or inferior vena cava.

4. Pulmonary and systemic blood pressures were practically identical in all varieties of Eisenmenger's syndrome in which the shunt was at aorto-pulmonary or ventricular level (Fig. 8). Their unity was preserved in the presence of any agent which normally influences one or other circulations more or less selectively—for example, exercise, pulsus alternans, ectopic beats, systemic vasodilators such as amyl nitrite, and systemic vasoconstrictors such as noradrenaline. This is well illustrated by the effect of the Valsalva manoeuvre (Fig. 9).

FIG. 9.—Identical pressures in the right brachial artery and pulmonary artery during the Valsalva manoeuvre in a case of Eisenmenger's complex.

5. Shunts were bidirectional rather than wholly reversed in 42% of cases with patent ductus, 90% of those with ventricular septal defect, and 85% of those with atrial septal defect. The left-to-right component of a bidirectional shunt commonly increased the oxygen saturation of samples from the relevant chamber and beyond by about 10%; the average increase was 8.6% in patent ductus, 14.5% in ventricular septal defect, 16% in single ventricle, and 13% in atrial septal defect, omitting from the calculations cases in which the shunt was wholly reversed or absent altogether. In two cases of patent ductus there was no shunt either way.

6. Pulmonary incompetence increased the oxygen saturation or right ventricular samples in cases with aorto-pulmonary bidirectional shunt, and tricuspid incompetence influenced right atrial samples similarly in cases with bidirectional ventricular shunt.

7. The pulmonary blood flow ranged between 2 and 7 litres per minute in all groups, and averaged 4 litres per minute. The pulmonary/systemic flow ratio averaged close to unity, and never exceeded 1.75. The oxygen saturation of samples from the pulmonary artery rarely exceeded 75 to 80%.

FIG. I.—Angiocardiogram showing a left-sided ascending aorta in a case of Eisenmenger's syndrome associated with transposition or corrected transposition.

8. The pulmonary vascular resistance ranged between 10 and 45 units (800 to 3,600 dynes sec./cm.²), and averaged 22 units in patent ductus, 20 units in Eisenmenger's complex, and 17 units in atrial septal defect. When considering the resistance, due allowance should be made for the smaller blood flows of infants and small children.

9. The arterial oxygen saturation (femoral in cases of patent ductus) averaged between 77 and 82% in all groups, and was remarkably close to the mean in three-quarters of all cases.

[The second part, together with a list of references, will appear in our next issue.]

ARTERIAL OCCLUSION COMPLICATING THORACIC OUTLET COMPRESSION SYNDROME

BY

C. G. ROB, M.C., M.Chir., F.R.C.S.

AND

A. STANDEVEN, M.Chir., F.R.C.S., F.R.C.S.Ed.
Assistant, Surgical Unit, St. Mary's Hospital, London

It is well known that a cervical rib, a fibrous band in the anterior border of the scalenus medius, or an enlargement on the first rib may cause symptoms of vascular disease in the upper limb, but it is less well appreciated that the result may be a major amputation, ischaemic contracture of the fingers, or ischaemic muscle pain in the forearm and hand. Three cases have been recorded in the literature in which proximal spread of arterial thrombosis had reached the bifurcation of the innominate artery and caused hemiplegia. We believe that this complacency may be attributed to the excellent collateral circulation in the upper limb, which in the more minor lesions leads to minimal symptoms and spontaneous recovery; to the still widely held theory of a nervous origin for these symptoms, leading possibly to inadequate examination of the patients' vessels; and to the paucity of cases of major arterial occlusion due to cervical rib recorded in the literature. The admission of six such patients to this unit within the past 12 months, however, suggests that the incidence of these major occlusions may be higher than is generally realized.

In 1911 Todd, having noticed that the lowest trunk of the brachial plexus is intimately related to a cervical rib more often than is the subclavian artery, suggested that vascular symptoms associated with such a rib might be due to paralysis of the sympathetic fibres running in this trunk. With increasing knowledge of the function of the autonomic system, Telford and Stopford (1931) rightly pointed out that the colour changes induced are those of overactivity, not of paralysis, of the sympathetic fibres. By administration of ergot they induced end-arteritis and thrombosis of the vessels in the combs of cocks and concluded that if arterial "spasm" be continued for a long period occlusion of the affected vessels can occur, and that irritation of the sympathetic fibres can occur, and that irritation of the sympathetic fibres crossing the cervical rib in the lowest trunk of the brachial plexus would thus explain all the vascular features seen in these patients, including disappearance of the brachial pulse. Moreover, they showed by a series of dissections that in some subjects the sympathetic fibres are aggregated into a bundle in the lower

part of this trunk, and argued that only in such a patient could these fibres be irritated, thus explaining the much greater incidence of neurological than of vascular symptoms associated with cervical rib.

Lewis and Pickering (1934) exposed the shortcomings of this theory by pointing out, firstly, that chronic irritation of a nerve trunk results in paralysis, not stimulation, of the fibres, and that there appears to be no reason why autonomic fibres should behave differently; and, secondly, that in cases of cervical rib the patients with vascular symptoms rarely have neurological features, whereas on the basis of this theory mixed cases should be regularly seen. Their own patient showed periarterial fibrosis, and it was demonstrated at operation that the subclavian artery was nipped between the abnormal rib and the clavicle when the arm was abducted. They suggested, therefore, that in these cases damage to the subclavian artery is followed by local mural thrombosis and that all the vascular features can be explained by embolism or by spreading thrombosis. Eden (1939) strongly supported this theory with the evidence of two further cases, and we submit that our experiences can be explained on no other basis. Support for this theory is also to be found in the not infrequent occurrence of a systolic murmur over the subclavian artery in these patients, indicating turbulence in the blood flow at this point.

Brachial Artery Occlusion

In patients with occlusion of the brachial artery a careful history revealed that a sudden onset of ischaemic symptoms in the hand and forearm was followed by a gradual recovery which may have been marred by one or more further acute episodes. On examination a powerful brachial pulse ceased abruptly in the vicinity of the lower border of the pectoralis major or the middle of the arm, points corresponding approximately to the origins from the brachial artery of major collateral vessels. After treatment, or even spontaneously, pulsation may return in the radial artery, though not in the lower brachial artery. These are the typical history and findings of a brachial embolus, which affords a much more convincing explanation of such a clear-cut picture than does a series of events consequent on sympathetic irritation. Injury may play a part in liberating an embolus, as illustrated by Cases 1 and 2, and may be a single blow or the repeated minor traumata associated with a particular occupation.

Case 1

A man aged 46 gave the history that following a fall on to his outstretched left hand at the end of February, 1957, the hand had suddenly become "numb," painful, cold, and white. On March 3 at another hospital a left upper thoracic ganglionectomy was performed, following which he noticed a pulsating swelling in his neck but no improvement of his hand. On March 17 he again had sudden severe pain in his hand, with marked pallor and coldness, and a brachial embolectomy was attempted but with only transient success.

He was admitted to our wards on June 28 with gangrene of the tips of the thumb and index and middle fingers and ischaemic atrophy of the hand. All the interphalangeal joints were almost fixed and movements at the metacarpophalangeal joints were greatly restricted by ischaemic contractures. The hand was white when elevated, cyanosed when dependent. The pulsation in the neck was the subclavian artery, which showed no aneurysm but was more prominent following division of the scalenus anterior at the sympathectomy. The brachial pulse ceased abruptly at the middle of the arm. X-ray examination showed no cervical rib, but a large boss on the first rib in the region of the subclavian groove.

At operation on July 10 the left first rib was removed, following which the colour and temperature of the hand

slowly improved, but when last seen there had been little improvement in the movement of his fingers.

Comment.—The sequence of events in this case appears to have been mural thrombosis of the subclavian artery, dislodgment by the fall of an embolus which lodged at the brachial bifurcation, and consecutive thrombosis to involve collaterals on March 17, removal of this clot being followed by thrombosis. The end-result is loss of the tips of the thumb and index and middle fingers and of 75% of the function of the hand.

Case 2

A man aged 22 was transferred to our ward from another hospital on May 11, 1957. In November, 1956, he used a Kanga drill at work for a day and a half, but thereafter did not use it again, as it caused considerable discomfort in his right upper limb. In December he suddenly developed pain in the right hand and numbness and tingling of the fingers, but spontaneous recovery began a few hours later. At the beginning of May, 1957, he experienced pain of sudden onset in his right hand and forearm, which became white and cold as high as the elbow, but, anticipating spontaneous cure as on the previous occasion, he did not seek advice for several days, by which time established gangrene of the fingers was found. He was at once admitted to hospital, where a brachial plexus block was performed and tolazoline hydrochloride injected intra-arterially. These measures had little effect and he was immediately transferred to St. Mary's Hospital.

On admission he complained of pain in the hand at rest, with severe pain in the forearm on movement of the fingers or wrist. The limb was cold and blue from the elbow downwards with diminution of sensation to pinprick and complete loss to light touch. There was dry gangrene of the three middle fingers and of the terminal phalanges of the little finger and thumb. The axillary pulse was strong but ceased abruptly at the lower border of the pectoralis major muscle. X-ray examination revealed a complete cervical rib.

The limb was cooled by exposure to a stream of air from an electric fan and vasodilatation encouraged by applying heat to the body and remaining limbs and by the administration of alcohol. Heparin was given intravenously to diminish the risk of arterial thrombosis in those vessels still patent. These measures produced little change in the appearance of the limb but averted spread of gangrene. On May 13 the cervical rib was excised with its periosteum and upper thoracic ganglionectomy performed. Post-operatively reflex vasodilatation and anticoagulant therapy were continued, and gradually the area of threatened gangrene receded distally. Amputation was postponed until July 24, when a line of demarcation was well established and it was possible to save the proximal part of the hand and portions of the thumb and little finger as a basis for later fashioning of a claw hand.

Comment.—This case also shows how a warning embolus may be followed by a more serious one with disastrous results. It also points the moral that amputation in embolic vascular disease should be delayed until the gangrenous tissue is clearly demarcated, for the line is almost invariably much more distal than the initial appearance would suggest. On admission the general impression was that nothing could save this young man from a formal below-elbow amputation.

Case 3

A girl of 15 years was admitted to hospital on January 26, 1957. Eight months previously she had developed tingling in the right hand and fingers and had noticed that the hand became white and painful if held above her head. Six weeks before admission the tip of her little finger became blue, as did the middle one shortly afterwards. Two weeks before admission she developed sudden severe pain in the forearm and hand, which became cold and white and later became cyanosed.

On admission the right forearm and hand were colder than the left and there was gangrene of the tips of the middle and little fingers. The whole hand was a dusky blue colour and little movement of the fingers was possible. On the right side of the neck a cervical rib was palpable with a prominent subclavian artery, over which a systolic murmur was clearly heard. No pulsation could be felt below the middle of the arm, at which point the brachial pulse ceased abruptly.

On January 28 a complete cervical rib was removed and upper thoracic ganglionectomy performed. The hand immediately became much warmer, finger movements rapidly improved, and the gangrenous areas became demarcated.

Comment.—This case also illustrates the probability of further embolism if the first one is ignored, but fortunately in this case the result was less serious.

Case 4

A man aged 46 was operated upon elsewhere in February, 1956, for bilateral inguinal hernia and developed post-operative pulmonary collapse. Serial chest x-ray films revealed that during this period he sustained a stress fracture of the right first rib near the scalene tubercle. Just before Christmas, 1957, he noticed considerable aching in his right forearm during shaving, and he had to rest several times during this operation with the arm hanging down, but as he often suffered from rheumatic myalgic pains he was not unduly alarmed. As symptoms persisted, however, he reported to his surgeon at the end of January, 1958, and was referred to us with the correct diagnosis, for examination showed that the brachial pulse ceased abruptly just below the lower border of the pectoralis major and x-ray examination for cervical rib revealed a large mass of callus on the first rib. On admission to hospital on February 25 we confirmed these findings, but, in addition, pulsation had returned in the radial artery and a pulsating collateral vessel was found in front of the medial epicondyle of the humerus.

At operation on March 3 the subclavian artery was found to have a soft friable wall, and in fact ruptured when depressed by a finger. Upper thoracic ganglionectomy was performed after suture of the artery, but it was deemed wiser not to interfere with the first rib. Post-operatively the hand was warmer and was no longer cyanosed when dependent.

Case 5

A woman aged 32 was awakened by sudden severe pain along the inner border of the forearm and hand and she noticed that the hand quickly became cold and white. Attempts to use the hand increased the pain. The condition improved gradually during the next two weeks, but on raising the arm above the head the hand still became white and numb.

On admission to hospital at this stage in February, 1952, the left hand and forearm were paler and colder than the right and no pulsation was palpable below the middle of the arm. Cervical ribs were palpable on both sides of the neck with prominent subclavian arteries overlying them.

At operation the subclavian artery on the left side was found to be constricted between the scalenus anterior and the abnormal rib. Division of the muscle was followed by vessel. A complete cervical rib was excised and upper thoracic ganglionectomy performed. Post-operatively the hand became warm and pink and pulsation returned in the radial artery. Unfortunately it has not been possible to see this patient since her discharge from hospital.

Subclavian Artery Thrombosis

Complete occlusion of the subclavian artery is less common than embolism in these patients, but may occur as a consequence of local mural thrombosis in one of two ways. Firstly, the thrombus may increase in size until it

occludes the vessel. If this process occurs gradually one would expect the collateral circulation to increase steadily with decrease of the flow in the main vessel, and the distal vessels to remain patent. Symptoms would develop gradually and probably would remain minimal. On the other hand, rapid occlusion of the subclavian artery would cause symptoms of sudden onset with gradual improvement as the collateral vessels dilated. Stammers (1950) records such a case. Secondly, a brachial bifurcation embolus could be followed by consecutive thrombosis, in which case a sudden onset of symptoms would be followed by deterioration, either steadily or spasmodically, depending on the rate of spread of thrombosis. It is in this group that the risk of gangrene is greatest, for the major collateral channels are occluded at their origins from the main artery. Reviewing 29 cases which they were able to trace in the literature, Schein *et al.* (1956) point out that two out of four patients under 35 years sustained major amputations, and 11 of the 29 had minor amputations.

Case 6

A woman aged 37 was admitted to hospital in September, 1957. In 1947 she had noticed a hard swelling above the left clavicle which had been removed at another hospital but had recurred. At this time she had been told that she had an extra rib. In January, 1957, tingling in the fingers of the left hand, with a feeling of numbness, and pain in the forearm and hand on use developed, and the hand became cold. All these features began simultaneously and suddenly and she noticed that if she used cold water the hand rapidly became blue, but a pink colour was restored by warmth. Since January the symptoms had become gradually worse and the hand constantly blue and cold.

On examination there was a palpable left cervical rib with a visible subclavian pulse medial to it. There was no palpable pulse beyond the rib and the axillary artery could be felt as a solid cord as far as the lower border of the pectoralis major. The hand was cold and blue, the grip weak, ischaemic pain came on rapidly, and there was impaired sensation of the fingers.

At operation on September 18 the subclavian artery was found to be thrombosed from the point at which it crossed a cervical rib. The rib was removed and upper thoracic ganglionectomy performed. Post-operatively the hand became warm and pink but no pulsation had returned to the distal vessels when the patient was discharged from hospital.

Comment.—The original operation in 1947 was excision of a cervical rib, presumably subperiosteal as the rib re-formed, and the subclavian artery thrombosis may have been induced by the operative trauma. The interval of 10 years between operation and the onset of vascular symptoms, however, suggests that it was spontaneous. It is clear that subsequently thrombosis had spread distally to the upper arm.

Case 7

A man aged 55 was admitted to hospital on September 10, 1957. Four months previously he had dropped a cup of tea because his right hand had suddenly become weak, and soon afterwards his fingers began to tingle. Since that time he had noticed difficulty in using his right hand, numbness of his fingers, and pain in his forearm and hand on use. More recently the hand became blue but the other features remained unchanged.

On examination the right hand was cold and the fingers were blue. No pulsation could be felt in the limb or root of the neck. X-ray examination revealed a short cervical rib on the right side.

At operation the subclavian artery was found to be acutely kinked and narrowed over a stout cord-like structure passing from the end of the cervical rib to the first rib, and was thrombosed from this point distally. The rib and cord were excised and upper thoracic ganglionectomy was per-

formed. Post-operatively the hand became pink and warmer, but the tingling persisted in the fingers. Use of the hand was being regained slowly two weeks later.

Comment.—The severity of the initial symptoms suggests that they were due to a brachial embolus from the obviously traumatized subclavian artery, which in turn became thrombosed either by consecutive thrombosis or, less likely, by spread of the intramural clot, consequent on the reduced blood flow through the vessel.

Vascular Symptoms Associated with Cervical Rib

The majority of cervical ribs cause no symptoms, but their owners are no less liable to other disease than are their fellows. Consequently it is not surprising that patients are sometimes seen with both vascular symptoms and cervical ribs which are no more than coincidental.

Case 8

A woman aged 70 was admitted to hospital in the afternoon of October 11, 1957. At lunch her hand became suddenly cold and white and the least movement of her fingers caused acute pain in the forearm.

Examination revealed that the right hand and forearm were colder and paler than the left, the brachial pulse ceased at the elbow, and there was no radial pulse. X-ray examination showed bilateral incomplete cervical ribs. The limb was kept cool, the body heated, vasodilatation encouraged with brandy and tolazoline hydrochloride, and anticoagulants were given to limit thrombosis. Symptomatic recovery proceeded steadily and the radial pulse became palpable on October 18.

One month later the patient was readmitted with congestive heart failure, and it appears likely that the source of the brachial embolus was a myocardial infarct.

Case 9

A man of 75 years was referred to the out-patient department with gangrene of the tips of his middle and little fingers. The radial pulse was palpable and the hand warm, but the affected fingers were cold and blue. X-ray examination revealed bilateral cervical ribs. The diagnosis of digital artery thrombosis due to atherosclerosis was made and recovery ensued without active treatment.

Case 10

A girl of 19 years was admitted to hospital on December 6, 1956, with a typical history of Raynaud's phenomenon in the hands, and complaining also of cold feet and blue legs. On examination all the peripheral pulses were palpable, the subclavian arteries were elevated on cervical ribs, and over the left one a systolic murmur was clearly heard. X-ray examination confirmed the presence of bilateral complete cervical ribs.

At operation the left subclavian artery presented a palpable thrill and was nipped between the rib and a band passing over the vessel. The ribs were excised and upper thoracic ganglionectomy was performed.

Comment.—This girl had the sympatheticotonic conditions of Raynaud's phenomenon of the hands and also cyanosis of the legs in association with cervical ribs. Nevertheless, the subclavian murmur and the operative findings strongly suggest that mural thrombosis had developed as a result of the rib on the left side, and it may be that timely operation has prevented embolus or major thrombosis. When last seen in January, 1958, the upper limbs were symptom-free and the pulses normal.

Discussion

Normally the subclavian artery passes from the thorax to the arms in a smooth curve over the broad surface of the first rib. The effect of a cervical rib is to raise the artery in the neck, thus sharpening the curve, and it now crosses the comparatively narrow surface of the cervical rib or the

narrow rigid band connecting the tip to the first rib. Any drag on the arm, therefore, will angulate the artery over a rigid structure, and a common complaint of these patients is inability to carry a heavy package on the affected side. Case 7 illustrates this point well, and it affords a probable explanation of the attacks of Raynaud's phenomenon which form the only symptoms of an occasional patient with cervical rib. Eden (1939) described a case in which scalenotomy was ineffective in relieving symptoms and a second operation was required for removal of the underlying rib, and Smith (1940) recorded a case of subclavian artery thrombosis due to kinking of the vessel by a fibrous band in the anterior border of the scalenus medius.

Clearly, then, angulation alone by an abnormal structure may be sufficient in time to damage the vessel, but there is evidence obtained at operation in such patients that the artery may also be subjected to further compression between the abnormal structure and the overlying scalenus anterior or clavicle. Case 5 is an example of this, and Lewis and Pickering (1934) were able to demonstrate the nipping of the subclavian artery between a cervical rib and the clavicle in their patient when the arm was abducted. Patterson (1940) describes an interesting case in which symptoms occurred on the second side three years after operation on the first, and it was seen at operation that the artery was greatly compressed between a cervical rib and the scalenus anterior. Division of the muscle afforded only partial relief of the compression, but the artery became 40% larger when the rib was removed.

Periarterial fibrosis may or may not be present in these cases, but appears to afford no indication of the severity of damage to the artery. In Case 4, for example, little or no fibrosis was present, yet the artery was soft and dilated and so friable that it ruptured at the touch of a finger. Stammers (1950) had a similar experience, and Adson (1947) reported two cases of rupture of the artery after scalenotomy, one as the operation was being concluded and the second on the twelfth post-operative day. That Telford (Telford and Mottershead, 1947) found no periarteritis in many of his cases cannot, therefore, be used to support his theory.

It has been suggested as an objection to the occlusive explanation of vascular symptoms in these cases that ligation of the subclavian artery distal to the thyrocervical trunk causes no symptoms and hence a mural thrombus should not do so. In fact, it does not, until either it becomes a complete occlusion or is cast off as an embolus, when symptoms of some duration are produced. Transient Raynaud attacks are due to intermittent occlusion of the artery by increased angulation or compression. Hyperhidrosis is quoted as evidence in favour of Telford and Stopford's (1931) theory, but this is an uncommon symptom in cervical rib patients with vascular features and we see sporadically patients with hyperhidrosis but no evidence of cervical rib. It is our opinion that when the two conditions occur in the same patient they are not cause and effect but are purely coincidental.

Whichever theory one believes, there can be no doubt that once vascular symptoms appear the rib should be removed. To add upper thoracic ganglionectomy takes only a few extra minutes, and in our opinion should always be done to secure rapid and maximal dilatation of the collateral vessels around the block in the main channels. Theoretically, one should also excise the affected segment of subclavian artery to prevent further emboli or thrombosis, and replace it with a homograft to restore normal blood flow, and this is advocated by Schein *et al.* (1956). We believe, however, that these advantages are largely theoretical. In cases of brachial embolus the distal vessel is blocked and a graft will do no more to improve the circulation to the hand and forearm than a sympathectomy. After removal of the traumatizing rib it is probable that the mural thrombus will organize, that the risk of a further embolus is small, and hence there is little to be gained by thromboendarterectomy. On the other hand, there is an appreciable incidence of thrombosis of grafts in vessels of this size,

particularly if end to end; the collateral circulation in this region is excellent and we believe the extent and duration of the operation are not justified by the slight improvement to be expected over a sympathectomy.

The ideal would be to remove the cervical rib before vascular complications occur, but, as the great majority of these ribs never cause symptoms, clearly some selection would be required. We suggest that the presence of a murmur over the subclavian artery indicates turbulence in the blood flow due to the rib (or to athero-sclerosis) and that in such a patient serious consideration should be given to the advisability of operation. Telford and Mottershead (1947) have shown that so many normal persons can obliterate the radial pulse by various postural manoeuvres that these are quite valueless in cases of cervical rib. Adson's deep-breathing test, however, does not fall into this class, for it depends on the action of the scalenus anterior as an accessory muscle of respiration, and obliteration of the radial pulse by this means suggests compression of the subclavian artery between a cervical rib and the muscle. We suggest that, while this does not in itself constitute an indication for operation, such a patient should be watched for the development of a subclavian murmur or of vascular symptoms, and operation advised should either appear.

Summary

Attention is drawn to the serious results which may ensue if vascular symptoms in association with a thoracic outlet compression syndrome pass unrecognized or are disregarded; for, though they may be coincidental, not infrequently they provide the initial evidence of damage to the subclavian artery. The end-result may be loss of fingers, ischaemic contracture of forearm and hand, or a major amputation, following occlusion of the main vascular channels by embolism or thrombosis: examples of each are described.

Further evidence of the purely vascular origin of these symptoms as distinct from an indirect autonomic effect is presented.

Treatment is briefly discussed and suggestions are made for the selection of those patients with cervical ribs in whom vascular complications may arise and for whom excision of the rib should be advised.

Two new training films for nurses, on lifting patients, have been made by the Ministry of Health, with the help of the Central Office of Information. The first deals with the lifting of patients in hospital, and demonstrates diagrammatically with an animated skeleton the effect on the body of a good and bad lift, and how the latter can cause injury. Two basic ways of lifting are shown, the usual hospital one, and the shoulder (or Australian) lift. The second, which is primarily to help district nurses and health visitors, could also be of use to relatives who are nursing patients at home. Various everyday situations are illustrated, including the lifting by a district nurse of a helpless patient in a low bed, and in a double bed, in cramped surroundings and without other help. Both these films are 16 mm. and can be hired from the Central Film Library, Government Building, Bromyard Avenue, Acton, London, W.3, at 5s. for the first day and 1s. for subsequent days. The films may be purchased for £10 12s. 6d. for Part I and £8 10s. for Part II.

EFFECTS OF SALTS OF NICOTINIC ACID ON SERUM CHOLESTEROL

BY

RUDOLF ALTSCHUL, M.D.

Professor of Anatomy and Director of the Laboratory of Gerontology, University of Saskatchewan

AND

ABRAM HOFFER, M.D., Ph.D.

Assistant Professor of Psychiatry and Director of Psychiatric Research Division, Department of Public Health, University of Saskatchewan, Saskatoon, Canada

In 1955, 1956, and 1958 we reported that nicotinic acid (niacin) in relatively high doses—in man 1 g. or more per 50 lb. (44 mg. per kg.) body weight per day—in many instances decreases the serum cholesterol in man and rabbits, and in rabbits inhibits experimental cholesterol atherosclerosis. This has been fully confirmed by other authors (for man by Parsons *et al.*, 1956; Achor *et al.*, 1957; O'Reilly *et al.*, 1957; Parsons and Flinn, 1957; Goldner and Vachalek, 1958; and for rabbits by Merrill and Lemley-Stone, 1957).

There is the question whether such a high dosage is toxic, especially for the liver. A number of liver-function tests and other routine examinations on patients who were being given this treatment for relatively long periods revealed nothing abnormal. In experimental animals which had received still larger doses the results were most contradictory. In 1939 Unna pointed out that the toxicity of nicotinic acid, as reported by Elvehjem *et al.* (1938) for one single dog, was likely due to the high acidity of nicotinic acid rather than to a specific action. This was borne out by the innocuity of sodium nicotinate used by Ackermann (1912), whose experiment had been repeated by Elvehjem *et al.*, but substituting nicotinic acid for the sodium salt. Unna showed that the acid has a pH of 3.3, whereas a solution of sodium nicotinate, corresponding to 10% of the acid, has a pH of 7-7.1. Unna stated further: "Sodium nicotinate is completely dissociated in solution, and thus no difference in the action of this compound from that of the acid itself is to be expected."

Even after Unna had explained the toxic action of very large doses of nicotinic acid by its high acidity and suggested the use of its sodium salt in animal experiments, a number of authors have continued to study the toxic effect of large doses of nicotinic acid and to ascribe this effect to a specific action, thus disregarding the findings of Unna. Handler and Dann (1942) reported that rats fed a diet containing 2% nicotinic acid gained weight, but developed fatty livers, as established by their increased content in fatty acids. No microscopical examination was done. On the other hand, nicotinamide did not produce fatty livers, but arrested the growth of the animals. Contrariwise, Aschkenasy and Mignot (1946) found that nicotinamide did not arrest growth, but produced necrotic foci in the liver and an increase of its fat content. These last two changes were conspicuous when the animals were given a protein-free diet, less so when the feed contained casein. Finally, Janes (1953) found no alteration of liver lipids after injection of nicotinic acid into rats. There are also many contradictory reports on blood-sugar levels and

on liver glycogen after administration of nicotinic acid. Hallay (1957) and other physicians prescribe in many instances nicotinic acid for lowering the blood sugar in humans.

Animal Experiments

In animal experiments which we have performed in our laboratory on rabbits and on rats we have found that feeding of high doses of nicotinic acid caused no morphological or biochemical changes which could be ascribed to the nicotinic acid. This was especially clear in nine rabbits which had shown no pathological changes whatever, in spite of the fact that during 90 days they had received not only 45 mg. of nicotinic acid daily but also cholesterol. In four young rats, fed for 14 days a balanced diet containing 2% nicotinic acid, to duplicate the experiments of Handler and Dann (1942), the animals continued to gain weight, just as theirs did. When the rats were killed the microscopical examination showed, however, no signs of fatty liver and the chemical analysis gave no increase of total fat. It should be pointed out that in the experiments of Handler and Dann the dose of nicotinic acid per kilogram of body weight of the animal would correspond in an adult man of 70 kg. to 154 g. daily.

However, there are human cases reported in which the treatment with large doses (3 to 6 g. daily of nicotinic acid) had to be interrupted for certain periods, or discontinued altogether, because of intervening gastro-intestinal disturbances. According to Achor *et al.* (1957), in a series of 45 patients the treatment had to be abandoned in three cases on account of nausea and diarrhoea. In our opinion this may be due to the high acidity—that is, to an unspecific factor—rather than to a specific action of nicotinic acid. Therefore we decided to test large doses of buffered nicotinic acid in order to find out whether or not their effect on serum cholesterol is comparable to that of pure nicotinic acid. As a matter of fact, many clinicians who treat various diseases, but mainly such of the circulatory system, with small—that is, "vitamin"—doses of nicotinic acid do not use the acid proper, but either sodium or magnesium nicotinate, and that per os or by injections.

Present Investigation

We submitted a group of university students to a test in which they received 1 g. of buffered nicotinic acid (0.6 g. of sodium bicarbonate for each gramme of acid) three times a day for two weeks. This test is explained in Table I and

TABLE I.—Serum Cholesterol* Before and After Administration of Buffered Nicotinic Acid (3 g. per day)

Subject No.	Cholesterol (mg./100 ml. Serum)		
	Initial	After 7 Days	After 14 Days
1	218	160	142
2	178	143	132
3	252	225	235
4	175	152	132
5	223	214	196
6	198	182	162
7	232	195	188
8	222	166	156
9	162	176	167
10	178	141	135
11	149	130	132
12	230	335	163
Mean	201.4	184.9	161.7

* Determination by Schönheimer-Sperry's method, as modified by C. S. McArthur.

shows that relatively large doses of buffered nicotinic acid decreased serum cholesterol in young healthy adults. The decrease compares well with two previous tests on similar and partly identical groups in which unbuffered nicotinic acid had been used.

Treatment with buffered nicotinic acid for two weeks lowered the mean cholesterol level for the 12 subjects from

201.4 to 161.7 mg. per 100 ml. This difference is highly significant ($k=2.44$, $P=0.01$). The decrease after one week is statistically not significant, owing apparently to one very high reading for subject No. 12.

Six of the subjects had participated in an earlier experiment in which they received nicotinic acid. The change in cholesterol observed during the previous experiment is shown in Table II. Subject numbers for both tables are the same.

TABLE II.—Serum Cholesterol Before and After Administration of Nicotinic Acid (3 g. per day) (from Altschul and Hoffer, 1958)

Subject No.	Cholesterol (mg./100 ml. Serum)		
	Initial	After 7 Days	After 14 Days
1	202	179	148
2	200	160	146
3	200	182	161
4	235	207	200
5	206	155	148
6	197	157	173
Mean	206.7	173.3	162.7

The changes in cholesterol levels were practically identical in both experiments. In five of the subjects the decrease in cholesterol was within 8%.

In a previous study Hoffer and Callbeck (1957) found the following regression equation relating initial cholesterol level to expected decrease after two weeks' treatment:

$$y = 0.52x - 71,$$

where y = decrease in mg./100 ml.
 x = initial cholesterol level in mg./100 ml.

With this equation the predicted value in this study is 167.7, the actual 161.7.

These observations show that the response to both nicotinic acid and nicotinic acid buffered with sodium salts is practically identical.

Obviously, in those cases in which sodium intake should be kept low potassium bicarbonate can be substituted in any desired proportion for the sodium bicarbonate. A very practical preparation seems to be the following: to 500 ml. of distilled water containing 32 g. of sodium bicarbonate (or 16 g. of NaHCO_3 and 16 g. of KHCO_3) is added slowly 50 g. of pure nicotinic acid, preferably in a wide container, to avoid "overbubbling." Of this solution, 1 tablespoonful of 10 ml. will contain buffered nicotinic acid corresponding to 1 g. of pure nicotinic acid. The best way to take this seems to be 1 tablespoonful diluted in one glass of water after lunch, 2 tablespoonfuls in one glass of water after the evening meal. In case larger doses are required, the amount is increased in proportion. Sipping of this solution over a prolonged period (approximately 60 minutes) may decrease the vascular dilatation, which is in some sensitive people an unpleasant side-effect. Since this vascular reaction usually disappears after three to seven days, the precaution of sipping the solution may then be discontinued. Of course, for practical reasons, especially in those cases where the patients do not take their meals at home, nicotinic acid, sodium (and potassium) bicarbonate, and some starch may be pressed into effervescent tablets and dissolved prior to taking the drug, possibly again after the main meals.

Finally, sodium nicotinate may be prescribed in the pure form, but it seems to us that in this case an unnecessarily large amount of sodium is being given.

Summary

It seems well established that nicotinic acid in relatively high doses decreases serum cholesterol in healthy and sick human beings. The toxicity of the substance is discussed, and it is pointed out that the high acidity rather than a specific action may be responsible for the occasional disturbances, such as gastro-intestinal reactions.

Tests on 12 healthy young individuals showed that a buffered solution of nicotinic acid is as efficacious in decreasing serum cholesterol as is the pure nicotinic acid.

In cases of poor tolerance of nicotinic acid a solution of nicotinic acid buffered with NaHCO_3 (or NaHCO_3 and KHCO_3) deserves to be tried.

We are indebted to Mrs. M. E. Fedoroff for her untiring assistance. This work was supported by the Teaching and Research Fund, College of Medicine, University of Saskatchewan, and by a Public Health Grant (Canada).

ELECTRODIAGNOSTIC STIMULATORS

A REPORT BY A SUBCOMMITTEE* OF THE MEDICAL RESEARCH COUNCIL'S NERVE INJURIES COMMITTEE

Electrical methods have long been used in the diagnosis and prognosis of lower motor neurone disorders. Erb, in 1883, described the classical faradic-galvanic test, which until recently has been the main stand-by in the electrodiagnosis of neuromuscular disorders. It is now known that this test is merely an abbreviation of the full excitability characteristics of nerve or muscle as demonstrated by the intensity-duration curve. Serious criticism has been levelled against the faradic-galvanic test (Wynn Parry, 1953; Ritchie, 1954), and the test is now regarded as obsolete. The first attempt to describe the characteristic excitability of nerve and muscle was the voltage-capacity curve (Cluzet, 1903). The curves plotted by this means, however, are not reliable, as the normal error range overlaps intermediate zones between denervated and innervated ranges. Furthermore, there are considerable technical drawbacks to the test. This technique has now been superseded by the plotting of a full intensity-duration curve using valve-controlled generators. Bauwens (1941) was the first to design an accurate electronic stimulator for this purpose.

An intensity-duration curve allows the expression of the characteristic excitability of the tissue under test in graphic form. An electrical impulse lasting 100 milliseconds or longer is applied to the muscle under test. The strength of current required to elicit minimal contraction (rheobase) is measured and expressed in milli-amperes, or the potential difference required to produce this current is measured and expressed in volts. The

*The Subcommittee was appointed with the following membership: Professor J. Z. Young (chairman), Dr. P. Bauwens, Professor R. E. M. Bowden, Dr. E. A. Carmichael, Dr. F. S. Cooksey, Dr. G. D. Dawson, Sir Bryan Matthews, Professor A. E. Ritchie, Squadron-Leader C. B. Wynn Parry, and Dr. E. F. Mason (secretary).

duration of impulse is progressively shortened and the intensity of current required to produce minimal contraction is measured for each duration. A curve relating strength of current and duration of impulse is drawn.

In normally innervated muscles the intensity of current for minimal contraction is the same over a wide range of pulse durations, and has only to be increased when very short pulse durations are used. When muscle alone is being stimulated—that is, denervated muscle—the curve is no longer a horizontal straight line but rises steeply and no response is elicited at the shorter pulse durations. This is due to the much lower excitability (longer chronaxie) of muscle compared with that of nerve. During recovery—that is, partial innervation—the curve is broken, showing elements of each excitable tissue, muscle, and nerve. Fig. 1 shows the three classical

Fig. 1.—The three classical curves of normal, denervated, and recovering muscle. A=Normal curve. B=Partial denervation or reinnervation. C=Denervation.

curves of normal, denervated, and recovering muscle. It is shown that slight changes in the curve are significant, and are reliable indicators of changes in innervation. The main changes seen are in slope and threshold, and the appearance of kinks and discontinuities.

Current- and Voltage-calibrated Generators

Two main types of generator are used in clinical electrodiagnosis—the current-calibrated and the voltage-calibrated generator. The voltage-calibrated generator is one in which the output impedance is low (500 ohms or less at maximum output) and a known voltage is produced across the output terminals. A current-calibrated generator is one which has a high output impedance (100,000 ohms or more) and the current in the tissues between the electrodes is closely defined.

In 1948 the Ministry of Health asked the Medical Research Council for guidance concerning the best type of stimulator for routine clinical electrodiagnosis. The Medical Research Council, through its Nerve Injuries Committee, appointed a subcommittee on electrodiagnosis, whose deliberations are the subject of the present report. The first duty of the Committee was to review existing apparatus for electrodiagnosis and to produce a detailed specification for a diagnostic generator. A report (1948) on a widely used voltage-calibrated generator was made available to the Committee, and from this it was clear that it had several technical shortcomings, including errors in the pulse output. It was considered that a higher degree of precision was required in an instrument to be used for clinical electrodiagnosis, and also that more pulse durations should be available. The Committee accepted that a satisfactory

current-calibrated generator, designed by Dr. P. Bauwens, was in routine clinical use at St. Thomas's Hospital and elsewhere.

The Committee decided that the two types of generator should be critically compared. In view of the fact that no satisfactory voltage-calibrated generator existed for comparison with the current-calibrated generator, the Committee decided to draw up a specification and to subject a voltage-calibrated generator, made to this specification, to technical trials. The specification was that (a) there should be ten pulse durations of 300, 100, 30, 10, 3, 1, 0.3, 0.1, 0.03, 0.01 milliseconds; (b) three pulse repetition frequencies of 0.5, 5, and 50 pulses per second; (c) the generator should be accurate to plus or minus 10%; and (d) it should remain reliable over a long period of time.

In response to the Committee's request, the Technical Repair and Development Section, Royal Air Force No. 248 Maintenance Unit, Chessington, made a prototype to the above specification (R.A.F. stimulator type V). This apparatus was tested by Professor Ritchie in the physiology department of St. Andrews University. Professor Ritchie subjected the generator to ten months' continual laboratory use and pronounced the stimulator satisfactory (Report, 1950a). At the end of this period a technical check was made at Chessington and none of the parameters was found to have altered by more than 10% (Report, 1950b).

After consultation with Professor F. C. Williams, of Manchester University, an opinion on the circuit diagrams of the prototype voltage-calibrated generator was sought from the Telecommunications Research Establishment (T.R.E.), at Great Malvern, and the following comments were made: (1) The input could be improved by incorporating a voltage stabilizer. (2) The output impedance could be made lower with advantage. (3) The apparatus might not be easy to produce commercially.

Accordingly, T.R.E., in an attempt to overcome these criticisms, constructed their own apparatus according to the specifications laid down by the Committee. The T.R.E. stimulator and the R.A.F. type V stimulator were then subjected to comparative clinical and technical tests at R.A.F. Chessington (Report, 1952). It was found, as a result of these tests, that identical curves could be drawn with each stimulator (Fig. 2). It was concluded that, although the T.R.E. stimulator was theoretically more accurate, in practice the degree of accuracy provided was not called for, and therefore the considerable extra expense was not justified. (It has subsequently been found that the R.A.F. generator has presented no problems in commercial manufacture.)

The Committee was thus in possession of an accurate and satisfactory voltage-calibrated generator. The current-

Fig. 2.—Curves of the T.R.E. and the R.A.F. Type V stimulator. ———=T.R.E. stimulator. ———=R.A.F. stimulator. A=Normal curves. B=Denervation curves.

calibrated generator had not, however, been subjected to the same tests, and it was next decided to compare the current-calibrated generator of Dr. Bauwens and the voltage-calibrated generator produced by the R.A.F. at three centres—St. Thomas's Hospital, St. Andrews University, and the Medical Rehabilitation Unit, Royal Air Force, Chessington.

Results

Comparison of current-calibrated generator and voltage-calibrated generator (R.A.F. Chessington) (Report, 1953a).—Intensity-duration curves were plotted with both stimulators on 77 subjects, divided as follows: 50 subjects with normal muscles; 19 subjects with partially innervated muscles (peripheral nerve injuries and poliomyelitis); and 8 subjects with denervated muscles (peripheral nerve injuries and poliomyelitis). Each subject was tested first with one stimulator, and then immediately afterwards, without moving the electrodes, with the other stimulator, using the longitudinal reaction. The experiment was so arranged that each stimulator was used alternately first and second. Experiments were carried over a period of several months. Comparison of normal curves, plotted with the two stimulators, showed that the chronaxie estimated by means of the current-calibrated generator was some 40 times that of the voltage-calibrated generator, and thus the curves using the voltage-calibrated generator were further over to the left than the other (Figs. 3 and 4). Results on the abnormal muscles showed that the curves obtained with the current-calibrated generator tended to rise more steeply and at a longer pulse duration than those when the voltage-calibrated generator was used. It was found that the

FIG. 3.—Limits of normal current-calibrated generator.

FIG. 4.—Limits of normal voltage-calibrated generator.

voltage-calibrated generator was apt to reveal kinks and discontinuities more readily than the current-calibrated generator. In the 77 subjects tested in these experiments, all preferred the voltage-calibrated generator to the current-calibrated generator. In 9 patients (excluded from the series) the current-calibrated generator was not well enough tolerated for intensity-duration curves to be plotted. As one of the criticisms of the voltage-calibrated technique has been the supposed necessity for careful skin preparation prior to test, it was decided to determine the effect of not lowering the skin resistance. Experiments showed that, although the threshold of the intensity-duration curve might be higher without previous preparation, the shape of the curve was identical in every respect with curves plotted after the skin was prepared (Figs. 5-7).

Comparison of Current-calibrated Generator and Voltage-calibrated Generator (St. Andrews University).—Intensity-duration curves on 38 normal subjects were plotted, using both stimulators alternately. The results are shown in the Table. Conclusions from these experiments were as follows. (1) The voltage-calibrated instrument has an impor-

FIG. 5.—Intensity-duration curves using the constant-voltage stimulator on the right quadriceps muscle in a patient with poliomyelitis. The curves are characteristic of partial innervation. No skin preparation was used. The upper curve was the first curve obtained, and the curves were repeated with successive tests until they gave identical readings. After the fourth test, successive tests gave the same curve, represented in the lower curve. It is seen that, although the threshold is lower, the shape of the curve is the same.

FIG. 6.—Intensity-duration curves using the constant-voltage stimulator on the right quadriceps in a patient with poliomyelitis. The curves are characteristic of partial innervation. Electrical stimulation (faradism) was given immediately before the test. No other skin preparation was used. The upper curve was the first curve obtained. The test was repeated until successive readings gave identical results. The second and third curves were identical, and are represented in the lower curve. The skin resistance has been lowered appreciably by the electrical treatment.

FIG. 7.—Intensity-duration curves using the constant-voltage stimulator on the right deltoid of a patient with a partial lesion of the brachial plexus. Infra-red radiation was applied to the muscle for 15 minutes immediately before the test. Dotted curve—first curve obtained. The test was repeated until successive readings gave identical curves. The second and third curves were identical, and are represented by the continuous curve. The infra-red radiation has successfully lowered skin resistance.

Results in 38 Normal Subjects

	Preferred C.V.	Preferred C.C.	Indifferent
Radial muscle (minimal preparation)	31	2	5
" (thorough ")	25	5	8
Facial muscle (minimal ")	38	(6 would not tolerate)	None
" (thorough ")	32	(4 would not tolerate)	2

tant advantage as regards comfort, which in a number of cases makes all the difference between getting a good record and getting none. (2) Thorough skin preparation tends to diminish the discomfort discrepancy, but not significantly. (3) Skin preparation has very little effect on the slope of the curves; in both cases the rheobase is lowered with preparation, and is more lowered in the case of the voltage-calibrated output. The rheobase of the current-calibrated instrument is not in practice sufficiently independent of preparation to make this an important claim. (4) The curve slope is influenced by pain to a greater extent than might be supposed. No doubt this is due to tenseness on anticipation of the shock, and we are devising experiments to show whether this is so or not. It was the impression that the "current" curves were less regular (and therefore less apt to reveal discontinuity in pathological cases) because of the increased tone of the muscle (due to discomfort), and that this was especially so in the important "middle region" of the curve.

Report of Comparison of Voltage-calibrated Generator and Current-calibrated Generator (Report, 1953b). (St. Thomas's Hospital).—Experiments conducted at this centre showed that when all precautions were taken with a voltage-calibrated generator it was as reliable and would give the same information as the current-calibrated generator. Tests were made in which the two electrodes connected to the sub-output terminals of the generator were applied to the subject's cheek while two pick-up electrodes connected to a D.C. amplifier proceeding into a cathode-ray oscilloscope were introduced into the mouth. With the voltage-calibrated generator it was clear that a very large peak occurred during pulse rate before the wave form reached a plateau. During pulse decay a surge in the opposite direction was noted. The current-calibrated machine gave a substantial rectangular voltage wave form. Except for a slight rounding off at the upper limit of the rising part of the pulse, the current-calibrated machine produced rectangular waves.

Conclusions

The following general conclusions were reached.

1. That both types of stimulator can provide the information required for assessment of the extent of muscle denervation.

2. For practical purposes of diagnosis, there appears to be no real sacrifice of accuracy by utilizing a voltage-calibrated stimulator. In fact, on sensitive subjects the voltage instrument is better tolerated, and this practical advantage from the subject's point of view outweighs any theoretical advantage of the high-impedance current-calibrated generator.

3. The detection of discontinuities in intensity-duration curves is the most reliable indication of partially innervated states. These discontinuities can be demonstrated by the use of both current- and voltage-calibrated generators. There is some evidence to suggest that they are better seen when using a voltage-calibrated generator. The absolute values of the curve points are of relatively little significance in determining the presence or absence of partial denervation. When the voltage-calibrated generator is used the alterations in skin resistance do not affect the shape of the intensity-duration curves, although there is a slight effect upon the threshold of such curves. Alterations in skin resistance do not significantly alter the threshold or shape of the intensity duration curve when the current-calibrated generator is used.

4. On the evidence presented above the voltage-calibrated generator has the following positive advantages over the current-calibrated generator: (a) the impulse is better tolerated by sensitive patients; (b) the instrument may be easier to construct; and (c) it is more satisfactory for routine clinical electrodiagnosis.

5. While the balance of evidence might appear to be in favour of the voltage-calibrated generator for routine purposes, some authorities have a preference for current-stabilized rectangular pulses. In view of the valuable work which has been and is being done with equipment generating such pulses, it is not intended to suggest that the voltage-calibrated generator should invariably supersede the current-calibrated generator.

In the light of these general conclusions, the subcommittee considers the voltage-calibrated generator to be an adequate instrument for general use for the electrodiagnosis of neuromuscular disorders according to the following specification.

I. ELECTRICAL PERFORMANCE REQUIREMENTS

(a) **Pulse Duration.**—10 pulse widths shall be available as follows: 300, 100, 30, 10, 3, 1, 0.3, 0.1, 0.03, 0.01 milliseconds. Pulse width accuracy shall be $\pm 5\%$ or 1 microsecond, whichever is the greater.

(b) **Pulse repetition frequencies** shall be 0.5, 5, and 50 pulses per second.

(c) **Pulse amplitude** shall be 200 volts maximum for all pulses. An amplitude control in conjunction with a calibrating system shall be employed to set the output to the maximum value of 200 volts.

(d) **Output Control.**—The delivered output shall not differ from the indicated output by more than 10% for all pulses and repetition frequencies, including switching transients. An output dial, directly calibrated in volts, shall be employed in order to provide a greater effective scale length than the size of meter commonly employed.

(e) **Wave Form.**—This shall be essentially flat-topped for all pulses. Amplitude droop shall not exceed 10% on the 300 milliseconds and 5% on the remaining pulses. Rise and decay times shall be negligible compared with pulse width. In the case of the 0.01 millisecond pulse, permissible rise and decay times are 0.001 millisecond. Leading and trailing edges shall have no more than a single overshoot which shall not exceed 10% of amplitude.

(f) **Output impedance** shall not exceed 500 ohms at any point on the scale.

(g) *Audible Monitoring*.—There shall be an optional audible monitoring signal synchronized with the pulses.

(h) *Safety Precautions*.—One of the patient terminals shall be connected to earth and the case. Dangerous potentials shall be excluded from the patient's circuit in the event of valve or component failure.

II. CONSTRUCTIONAL REQUIREMENTS

Minimum constructional requirements shall be those set out in Inter-Service Specification R.C.S. 1,000. The subcommittee reports that one prototype fulfilling the above specification has worked satisfactorily for over five years.

The Subcommittee is greatly indebted to the following co-opted members who gave valuable assistance in the work: Messrs. Bannister, Bowes, Galloway, Spencer W. Noble, and Sutton (Technical Research Establishment, Great Malvern); Mr. R. Brennan (R.A.F.); and Mr. P. Stiles (St. Thomas's Hospital).

CULLEN'S SIGN

BY

E. F. B. CADMAN, M.D., M.R.C.P., D.C.H.
Consultant Physician, Southport Hospitals Group

In 1918 T. S. Cullen reported a case in which a blue discoloration of the umbilicus was noted. By analogy with a case described earlier by Ransohoff (1906), in which a localized yellow umbilical stain occurred, free bile being found in the peritoneal cavity at operation, Cullen correctly postulated the presence of a haemoperitoneum and, from other evidence, deduced the cause of this to be a ruptured tubal pregnancy. A number of similar cases have since been reported (Novak, 1922; Strube, 1923; Tanner, 1932; Smith and Wright, 1935). The operative findings of Stabler (1934) and Way (1941) showed that the skin discoloration was due to blood in the subcutaneous tissue, as in an ecchymosis. In the same way, therefore, as in this latter condition, the exact colour of the sign may vary (Jackson, 1922; Neumann, 1928; Fallon and Manning, 1949). The abnormal staining of the subcutaneous tissue need not be confined to the umbilicus (Neumann, 1928; Stabler, 1934; Fallon and Manning, 1949), and may even involve previous abdominal operation scars (Gold, 1926; Schmitz, 1932; Smith and Wright, 1935). In all, it has been possible to trace about 30 reported cases of Cullen's sign associated with ruptured tubal pregnancy, though Fallon and Manning (1949) claim to have found 70 such instances.

Two years after Cullen's original description, Turner (1920) described two cases of acute pancreatitis. The first exhibited a somewhat extensive Cullen's umbilical sign accompanied by free intraperitoneal fluid, and eight similar cases have since been recorded (Johnston, 1930; Petrivalsky, 1931 (3 cases); Stutzer, 1931; Fallis, 1937 (3 cases)). Turner's second case showed a dirty green loin discoloration due to direct tracking of pancreatic fluid to the subcutaneous tissue. It is to this latter sign

that the eponym "Grey Turner's sign" has been applied (Wakeley, 1952; Bailey, 1954). Only two other examples of this sign have been traced in the literature (Cox, 1945; Kelley, 1957) and only the former was associated with pancreatitis. Although both signs are rare, Cullen's sign would appear to be more common in acute pancreatitis than Grey Turner's sign.

In view of the above discussion it is not surprising that Cullen's sign is commonly regarded as being due to a haemoperitoneum associated with a ruptured tubal pregnancy or, less commonly, acute pancreatitis (Bailey, 1954). The problem is not quite so simple, however, as the presence of Cullen's sign with either a ruptured tubal pregnancy or acute pancreatitis does not invariably imply the presence of a haemoperitoneum (Pfeiffer, 1923; Smith and Wright, 1935; Fallis, 1937). Further, the sign has been reported with numerous other conditions, with and without an accompanying haemoperitoneum.

Of these alternative causes, the most frequent is rupture of the rectus abdominis muscle, when the skin discoloration may occur at the umbilicus (Perman, 1922; Von Renner, 1924; Halperin, 1928; Way, 1941) or elsewhere (Stoeckel, 1901; Cullen and Brödel, 1937 (Case 2); Teske, 1946). No blood was present in the peritoneal cavities of any such cases except for that described by Toft (1915).

The occurrence of Cullen's sign with ante-partum rupture of a caesarean section scar was first reported by Gerrard (1938), no free blood being present in the peritoneal cavity. Similar cases have since been recorded (Galloway, 1939; Gough, 1939; Way, 1941). Finally, Cullen's sign has been noted in association with the following conditions: acute salpingitis (Schumann, 1923; Hadley, 1940); haemorrhagic ascites (Sternberg, 1922; Kapsinow, 1925); haemorrhage in association with acute yellow atrophy of the liver (Schumann, 1936); ovarian cyst (Busch, 1922); and traumatic haematoma of the cave of Retzius (Goinard and Curtillet, 1934).

The exact significance of Cullen's sign is thus open to doubt. Interest in the mode of production and significance of the sign was stimulated by the observation of Case 1 described below. Two earlier examples were then reviewed (Cases 2 and 3). It is considered that a study of these three cases throws light on some of the unanswered problems. The present paper is only the fourth occasion on which as many as three cases of Cullen's sign have been reported together (Petrivalsky, 1931; Fallis, 1937; Way, 1941). In none of these 12 patients was the cause a ruptured tubal pregnancy.

Case 1

One week before being seen on August 18, 1956, a 67-year-old man suddenly developed severe lumbar backache radiating into the left leg. He was tender over his left sacro-iliac joint and there was limitation of the straight-leg raising test on the same side.

He improved with bed rest, but had a severe recurrence on October 21 and morphine was required. The next day he had a florid complexion with a B.P. of 120/80 mm. Hg and a haemoglobin of 8.7 g./100 ml. He was tender in the left loin posteriorly, and anteriorly a large tender non-pulsatile mass was palpable. An x-ray film showed a large calcified abdominal aortic aneurysm extending to the left of the spine. Two days later the abdominal mass was more tender, there was blueing at the umbilicus, and the central part of the mass was pulsatile. Twenty-four hours later

shock developed, the blood pressure falling to 90/60 mm. Hg, the pulse rate rising to 104, and the haemoglobin falling to 4.8 g./100 ml. Blood transfusions and morphine were given, but he died the following day.

Post-mortem examination revealed an obese pale man with umbilical blueing which on incision was seen to be due to blood in the subcutaneous tissues. The heart showed evidence of an old coronary thrombosis, and there was some pulmonary congestion. On opening the abdominal cavity dark blood was seen extraperitoneally on the left side deep to the abdominal muscles. Anteriorly this could be followed to the extraperitoneal tissue deep to the umbilical scar, superficial to which was the blood-stained area of subcutaneous tissue. There was a small break in the continuity of the blood about 1 cm. wide. This was situated about 3 cm. from the umbilicus, but on massaging this area the two patches of blood easily joined. Posteriorly the extraperitoneal blood was continuous with a large retroperitoneal haematoma migrating from a ruptured saccular aneurysm, 10 cm. in diameter. This arose from the abdominal aorta below the left renal artery. There was no blood in the peritoneal cavity.

Case 2

A 39-year-old woman was first seen in March, 1949, being under the care of Lord Cohen of Birkenhead. Three months previously she had developed an influenzal-like illness followed one month later by diarrhoea which had persisted. A month before she was seen, swelling of the legs and face developed. Clinically her general condition was quite good, but some oedema of the lower trunk, legs, and face was present. There was a suggestion of ascites, but nothing else abnormal was detected in the heart, lungs, or abdomen. Urinalysis revealed a trace of albumin. A little later a blue discoloration was noted at the umbilicus and a vague mass was felt under the right costal margin. Vaginal examination suggested the presence of a high pelvic mass. Abdominal paracentesis was carried out, 7 pints (4 litres) of heavily blood-stained fluid being obtained. Following this the liver was felt to be enlarged. Later the patient developed jaundice, finally dying 15 days after Cullen's sign had been noted.

Post-mortem examination showed a body with marked icterus and Cullen's sign still visible. The abdomen was distended and 3½ pints (2 litres) of blood-stained peritoneal fluid was present. Nodules of tumour were revealed in the fluid was present. Nodules of tumour were revealed in the liver and over the pelvic organs. A large carcinomatous ulcer was present in the hepatic flexure of the colon with extensive retroperitoneal haemorrhage arose from these. There was widespread lymph node involvement of the para-aortic chain. A little fluid was present in the left pleural space and a terminal bronchopneumonia was also found. Histologically the growth was a spheroidal cell carcinoma.

Case 3

On April 8, 1954, a 71-year-old woman was admitted to the Liverpool Royal Infirmary under the care of the late Mr. M. Silverstone. She had always been constipated, but more recently had developed periumbilical pain radiating round from the back and she had noted that her abdomen was swollen. The patient was pale (haemoglobin 7.5 g./100 ml.). The abdomen appeared distended and there was doubtful shifting dullness. A barium-enema x-ray examination was normal apart from evidence of a large soft-tissue pelvic swelling lifting up the colon. A few days later a blue discoloration was noted around the umbilicus. Vaginal examination confirmed the presence of a mass to the left of the uterus. After blood transfusions, operation was performed on April 20. A haemoperitoneum was found with old blood adherent to the small bowel and sigmoid colon. Blood adherent to the uterus, which was itself enlarged. Total hysterectomy was performed, including most of the mass but leaving behind the tubes and ovaries. Some of the mass had to

be left in the outer end of the broad ligament into which it extended. The patient made a good recovery.

Examination of the specimen showed a uterus enlarged (10 by 5 by 7 cm.) by several intramural fibromyomas and containing in the cavity two large endometrial polyps and one small endocervical polyp. Adherent to the left and posterior surfaces of the uterus was a collapsed cystic tumour, 10 cm. in diameter. It was continuous with a soft intramural fibromyoma. The wall of the cavity was thick and ragged, suggesting a degenerated fibromyoma. Histologically it was an undifferentiated tumour, probably of mesenchymal origin (Mr. S. Bender).

Discussion

Two earlier theories have been propounded to explain the development of Cullen's sign, but each of these immediately runs into difficulties, as the presence of a haemoperitoneum is essential to both. As is emphasized by Case 1 (and others already enumerated) this is not an invariable accompaniment of the sign. Conversely, the sign is very uncommon in the presence of the relatively frequent states of haemoperitoneum (Case 3) or haemorrhagic ascites (Case 2; Sternberg, 1922; Kapsinow, 1925).

In the first theory the presence of an anatomical defect of the umbilical parietal peritoneum was suggested. There are undoubtedly small blind pits in this region (Cullen, 1916) but the peritoneum is intact in them. This is true even in the case of an umbilical hernia, and, in any event, on embryological grounds no such defect is to be expected.

The alternative theory assumes a physiological breach in the umbilical peritoneum whereby blood pigment is taken up by the local lymphatic vessels and deposited in the nearby subcutaneous tissue. That such lymphatic vessels exist is well known (Cullen, 1916), but there is no evidence that selective absorption takes place at the umbilicus (Higgins and Graham, 1929); and, secondly, it is the role of lymphatic vessels to remove such pigment to the regional lymph nodes and not to deposit it *en route* in the subcutaneous tissue.

The occurrence of secondary carcinomatous deposits at the umbilicus lends little support to the above theories, as in the first place such tissue is invasive and need not necessarily follow anatomical pathways. Secondly, it is rarely certain whether the spread has been transperitoneally or extraperitoneally, from the upper abdomen via the liver and its round ligament, or from the pelvis via the obliterated hypogastric arteries or urachus. Likewise the exact reason for the development of umbilical endometriosis is unknown.

Theory of Extraperitoneal Spread of Blood

The findings in Case 1 were unique. In this example blood could be traced extraperitoneally (with only two small interruptions) from a retroperitoneal source (ruptured aortic aneurysm) to a Cullen's sign. An abdominal wall ecchymosis with a ruptured abdominal aortic aneurysm is extremely rare (Beebe, Powers, and Ginouves, 1958). Case 1, therefore, gave powerful support to a third theory that the basic underlying cause of Cullen's sign was the extraperitoneal spread of blood and that the occurrence of a haemoperitoneum was purely fortuitous. This hypothesis was originally proposed by Fallis (1937), who described two cases of acute pancreatitis which showed the sign. Although neither had any free intraperitoneal fluid, both did exhibit extensive retroperitoneal and extraperitoneal haemorrhage. In the same way, Cases 2 and 3 described above did show possible essential prerequisites for the production of the sign, though both also exhibited intraperitoneal fluid. In Case 2 there was extensive retroperitoneal and mesocolon haemorrhage, whilst in Case 3 the vascular tumour burrowed out into the broad ligament towards the lateral pelvic wall. In neither case was there a simple clear-cut rupture of a blood vessel into the peritoneal cavity.

There is much additional evidence to support this theory. The anatomy of the extraperitoneal space has recently been

1956-7.—The scope of the investigation was changed during this period. At two recruit stations, between November, 1956, and April, 1957, throat swabs were taken from all patients admitted to sick-quarters with respiratory illness for more than 48 hours; standard record cards were again completed by the unit medical officer. At one of these stations all patients had their chests radiographed within seven days of admission, and paired samples of blood were taken from all patients with evidence of pneumonia. Detailed results of this study are to be reported elsewhere (J. N. C. Cooke and J. Gilroy, 1958, personal communication). At two other recruit stations visits were made by one of us at two-weekly intervals. Throat swabs and records were obtained at this time from all patients admitted with acute respiratory illness within the previous 48 hours. Twenty-seven other stations of various types—boys' units, technical training schools, and operational units—notified their weekly incidence of respiratory disease. Whenever there appeared to be an outbreak the station was visited and a number of patients were examined and records and specimens obtained.

Records of Invaliding.—The records were examined of all Service men with more than two weeks' service invalided in 1953 and 1954 for any respiratory illness except tuberculosis and cancer.

Laboratory Methods.—Throat swabs and sera were stored at -30°C . until tested; details of the tests used have been described previously (Kendall *et al.*, 1957) and are therefore only outlined here. Serological diagnosis was made by means of the complement-fixation test. Partially purified soluble antigens prepared in fertile hens' eggs were used for influenza viruses A and B, and heated but otherwise untreated fluids from HeLa cell cultures infected with RI-67 (adenovirus type 4) were used as the adenovirus group antigen. Adenovirus isolation tests were done in HeLa cell tube cultures which were kept a minimum of 10 days before being reported negative. Adenovirus strains were identified by the complement-fixation test and were typed in HeLa

cell cultures by neutralization tests using specific rabbit sera. Two hundred and fifty-seven serum pairs, comprising almost all those collected between February 10 and March 19, 1958, were also tested by Dr. P. S. Gardner for evidence of Sendai virus infection (Gardner, 1957).

Results

1. Prevalence of Respiratory Illness

Fig. 1 shows respiratory disease admission rates for periods of four weeks in various types of unit in the two winters studied. Incidence was highest in recruit stations in both winters, reaching 9% to 10% of the population at risk, but persisting longer in 1955-6 than in 1956-7. Non-recruit units had a much lower incidence, rising to just over 1% in February, 1956, and in March, 1957. Admission rates in boys' units lay between these two, and ranged from 2% to 6%; rates were high in the autumn of 1955, in March, 1956, and in February, 1957.

2. Laboratory Results

1955-6.—In recruit units, of 281 pairs of serum tested, 72 (26%) were positive for adenovirus and 13 (5%) for influenza A. In non-recruit units the proportion positive for adenovirus was much lower. Of 379 pairs of serum from boy entrants, 12 (3%) were positive for adenovirus and 15 (4%) for influenza A. Of 1,015 pairs from patients in operational units, 44 (4%) were positive for adenovirus and 146 (14%) for influenza A, and one was positive for both; in addition two patients showed a rising titre against influenza virus B, and five against Sendai virus. Fifty-two adenovirus strains were isolated, all but one from recruits; 35 of these were typed, and all belonged to type 7. The time distribution of the main serological results is shown in Fig. 2.

These findings probably give a reasonable indication of the relative frequency of adenovirus and influenza A infections in the three types of unit. But the considerable differences in the incidence of respiratory illness shown in Fig. 1 must influence any estimates of illness attack rates due to these agents. The proportion of illness due to influenza A was lower in recruits than in non-recruits, but the attack rate due to this virus must have been almost twice as high. By the same argument the influenza A attack rate in non-recruits was probably very little higher than in boy entrants. The adenovirus experience was quite different, both the proportion of illness and attack rates being much higher in recruits. During the months of February, March, and April, when monthly respiratory admission rates in recruit units approached 10%, over half the paired sera tested were positive for adenovirus. On the other hand, the incidence of illness due to adenovirus among non-recruits and boy entrants was low.

FIG. 1.—Respiratory illness admission rates, 1955-7.

FIG. 2.—Serological results, 1955-7.

Excluding recruits, the age of patients with adenovirus infection tended to be lower than that of those with influenza A. Only 3 (5%) of the 56 positive for adenovirus were over 25 years of age, and two of these were medical officers; 28% of those with influenza A were over this age.

1956-7.—The most notable feature of the results obtained during this winter was the almost complete absence of adenovirus infection in the recruit units. From 1,110 throat swabs tested in HeLa cells only four strains were isolated—three of type 3 and one of type 4. The only other evidence of adenovirus infection was at a station for boy entrants where four strains—two of type 4 and two of type 7—were isolated during a small outbreak of respiratory illness at the end of March. Influenza A, on the other hand, was responsible for several outbreaks investigated at non-recruit and boys' units during February, March, and April, and in March it accounted for about half the cases with physical or x-ray changes in the chest at the recruit unit where paired sera from such patients were collected as a routine.

Clinical Observations

The symptoms and signs of acute respiratory illnesses due to a single agent vary considerably, and this tends to obscure differences between illnesses caused by one agent and those caused by another. No great diagnostic accuracy in the individual case can therefore be expected from clinical examination alone. Some differences were apparent, however, in the frequency of certain symptoms and signs between groups of patients with adenovirus infection, influenza A, and other acute respiratory illnesses—almost all of unknown aetiology. This may be seen in the Table, which

Clinical Findings and Serological Results on Non-recruit Units, 1955-6

	Influenza A	Adenovirus Infection	Remainder*
No. illnesses	161	56	1,177
No. with adequate record	161	56	1,140
Symptoms present (%):

* All serologically negative except two patients with a rising titre to influenza virus B, five to Sendai virus, and one to both adenovirus and influenza virus A.

summarizes the clinical records of non-recruits during the 1955-6 survey. Cough, muscular pains, and a temperature of 102° F. (38.9° C.) or more were rather more frequent in those with influenza, and sore throat in those with adenovirus infection. It is interesting that conjunctivitis was more frequent in those with influenza, but it is doubtful whether the conjunctivitis seen in Service men during the winter months was of the same type as that noted in schoolchildren during summer outbreaks of pharyngo-conjunctival fever (Kendall *et al.*, 1957).

Invaliding

In the years 1953 and 1954, 195 men and women were invalided from the R.A.F. because of disease of the respiratory tract other than tuberculosis or cancer, and a disability pension was awarded to most of them. At least 90% of these were discharged because of bronchitis, bronchiectasis, these were discharged because of pneumonia, pulmonary fibrosis, or empyema. More than 40% served less than six months, and all of these had suffered as recruits from an acute respiratory illness from which they did not fully recover and which led directly to invaliding. A further 14% who had served less than one year had mostly been ill as recruits and spent almost the

entire period of their service in hospital. Recurrent respiratory disease played little part in the causes of invaliding; two-thirds suffered from only one illness during their service. A history of pneumonia or bronchitis before entry into the R.A.F. was recorded in 44% of those invalided with less than six months' service, but it is hard to know what importance to give to this observation.

The acute illness that led to invaliding was usually in the winter or early spring, during those months when the incidence of respiratory diseases is highest at recruit stations. About one in every 250 acute respiratory admissions at a recruit station led to invaliding before the completion of six months' service. This amounts to the permanent loss of perhaps one in every 1,000 airmen recruited during the first quarter of the year.

Discussion

Acute respiratory disease in military personnel is a serious problem. Not only is time lost during training but a substantial number are invalided with serious lung damage before any useful service has been performed. Among air crew respiratory infections have special importance because of pressure effects on the middle ear at high altitudes. In the Royal Air Force, the incidence of acute respiratory disease is highest by far in the recruit units. This is not an isolated finding, and has been reported not only in the United States of America but also in Switzerland (Löffler *et al.*, 1956) and Holland (van der Veen and Kok, 1957). The major cause of respiratory diseases invaliding in the R.A.F. is illness acquired at recruit camps. Time spent at these stations represents at most one-twelfth of the total service, whereas approximately two-thirds of all illness leading to this type of medical discharge is acquired during this period.

The adenoviruses and influenza viruses may well account for at least half the illnesses during the severe and protracted winter epidemics in recruit stations. In non-recruit units, as in the adult civilian population, the adenoviruses do not appear to be a frequent cause of illness; though most outbreaks were due to influenza virus, the cause of a relatively high proportion of acute respiratory disease requiring admission to sick-quarters remains unknown. Adenovirus infection may only be able to spread readily under the exceptional conditions of a recruit camp with its large and rapidly changing population of young men drawn from all parts of the country and introduced to residential community life for the first time. Apart from some radical change in recruit reception and training, effective vaccines, used if possible before arrival at the recruit units, would appear to offer the best hope of reducing the problem. Much can already be expected from influenza A vaccines, and field trials in the United States have shown that adenovirus vaccines are capable of affording a high degree of protection against viruses of the same type (Bell *et al.*, 1956; Stallones *et al.*, 1957).

Summary

In surveys of acute respiratory illness in selected R.A.F. stations in 1955-7 it was found that the incidence of sickness requiring admission to sick-quarters was far higher in recruit units than in operational stations.

Adenovirus infection was probably responsible for at least half the respiratory disease admissions in recruit units during the periods of highest prevalence in 1956, but was completely absent from the same units in 1957; it was responsible for very few admissions in other types of unit.

Influenza virus A was an important cause of illness among recruits in both winters, and accounted for at least 12% of respiratory admissions in other units in 1955-6 and for outbreaks at several stations in 1956-7.

More than half those invalided from the R.A.F. in 1953 or 1954 with a respiratory disease, other than

tuberculosis or cancer, were discharged as a result of an acute respiratory illness contracted during their recruit training.

We are indebted to the P.M.O. Technical Training Command, R.A.F., and other medical officers for granting us facilities to conduct these studies; to many station medical officers and in particular to Wing Commander M. Robertson, Wing Commander M. O. Richardson, and Squadron Leader W. G. Cooke for their co-operation in taking blood samples and completing the special records required; to Wing Commander R. J. A. Morris for help with records of invaliding; to Sergeant A. T. Coukham for valuable technical assistance; and to Dr. P. S. Gardner and Dr. G. B. Bruce White, of the Public Health Laboratory Service, for help with special laboratory tests.

DINITROPHENOL AND DIABETES MELLITUS

A COMPARISON WITH SALICYLATE

BY

JAMES REID, M.D., M.R.C.P.

Director, Clinical Chemotherapeutic Research Unit of the Medical Research Council, Western Infirmary, Glasgow

Salicylate and 2:4-dinitrophenol (D.N.P.) both inhibit oxidative phosphorylation (Loomis and Lipmann, 1948; Brody, 1956). Salicylate also controls the clinical and biochemical abnormalities in moderately severe diabetes mellitus (Reid, Macdougall, and Andrews, 1957). The question that arises is whether D.N.P. has a similar action in this disease.

D.N.P., a powerful metabolic stimulant, was grossly misused in the 1930's as a slimming agent. The principles for prolonged use of a dye substance in clinical medicine put forward by Shannon *et al.* (1944) were not fully appreciated, and the high incidence of serious toxic effects from prolonged administration led to its withdrawal as a therapeutic agent. Since then it has been used only occasionally in clinical practice, although it is still extensively employed in biological investigations.

A short, carefully controlled trial of D.N.P. in diabetes mellitus has been carried out to discover its effect on blood sugar, glycosuria, and glucose tolerance. Six elderly ladies with mild to moderately severe diabetes were investigated along the lines previously described in the aspirin trial. They were given a constant low carbohydrate diet (150 g.) for at least 10 days before starting D.N.P., to establish the effect of diet alone, and the same diet was maintained throughout the whole investigation.

D.N.P. was given for 14 days in doses of 100–300 mg. in capsules daily, actual doses being controlled by

repeated plasma drug levels (Parker, 1949) and by measurement of oxygen consumption of fasting, resting patients with a Benedict-Roth machine to calculate the basal metabolic rate (B.M.R.) (Robertson and Reid, 1952). An attempt was made to induce the same order of metabolic stimulation with D.N.P. as was previously induced in diabetics successfully treated with aspirin. The effects of D.N.P. on fasting blood sugar estimated by Lehmann and Silk's (1952) modification of Folin and Wu's method, on glycosuria determined by Benedict's (1911) method, and on oral glucose tolerance were examined. Since none of the patients had abnormal quantities of ketones in the urine, quantitative measurement was not undertaken.

Results

Dose of D.N.P., Plasma Level, and B.M.R.—Frequent determinations of plasma D.N.P. level and oxygen consumption were necessary to control therapy and to avoid

undesirable reactions. Table I gives relevant clinical particulars as well as doses and plasma levels of D.N.P. A fairly steady plasma concentration of D.N.P. was reached in each patient after the first day's dosage: the mean values of the six patients between the second and fourteenth days ranged from 34 to 48 mg./litre. The relation between plasma D.N.P. and the B.M.R. is shown in Fig. 1: an obvious and expected rise in B.M.R. accompanied an increase in plasma D.N.P. concentration. The regression line and its 95% confidence limits are shown. No toxic effects from D.N.P. were encountered, and the results, in addition to defining a significant relation between plasma D.N.P. and B.M.R., indicate that the same order of metabolic

Fig. 1.—Relation between the rise in B.M.R. from D.N.P. and the plasma concentration of the drug in six female diabetics. The regression line and its 95% confidence limits are shown. The coefficient of correlation, r , was 0.54 with $p > 0.01$, but < 0.001 ($t_{0.05} \times \sigma r = 26.5$).

stimulation has been obtained with D.N.P. as in an earlier investigation with aspirin in diabetes mellitus.

Fasting Blood Sugars.—Fasting blood sugars of the six patients at intervals throughout the investigation are shown in Table II. The values of each patient towards the end of the control dietetic period were close enough to one another

TABLE II.—D.N.P. and Fasting Blood Sugar

Case No.	Fasting Blood Sugar (mg./100 ml.)					
	Before D.N.P.		During D.N.P.			After D.N.P.
	Days 4–5	Days 0–1	Days 3–4	Days 7–8	Days 13–14	Days 3–4 Day 6
1	146	136	158	152	152	133
2	157	228	212	202	196	208
3	224	250	200	133	124	129

Mean	240	246	220	202	186	192

to indicate that a comparatively stable state had been reached from which the effect of D.N.P. could be judged. In the two weeks that D.N.P. was given the fasting blood sugar of the patient with the mildest diabetes increased a little. The values of the other five patients fell slightly, but in no patient did they reach normal. The group mean concentrations were: 246 mg. per 100 ml. on the day before or on the actual day D.N.P. was started and 186 mg. per 100 ml. after 14 days of D.N.P. administration. The hypothesis that the difference between the mean blood sugars immediately before and at the end of the D.N.P. course was zero was rejected because the t -test gave a value of p between 0.05 and 0.02. The fall in mean fasting blood sugar was therefore just significant.

Glycosuria.—The amount of sugar in the urine was estimated before, during, and after administration of D.N.P., and the results, shown in Table III, agree with the fasting

TABLE III.—D.N.P. and Glycosuria

Case No.	Urinary Sugar (g./24 hours)					
	Before D.N.P.		During D.N.P.			After D.N.P.
	Days 4–5	Days 0–1	Days 3–4	Days 7–8	Days 13–14	Days 3–4 Day 6
2	12	8	6	3	4	9
3	10	10	3	3	0	0
4	23	14	12	16	4	—
5	39	34	63	36	29	20
6	44	32	39	16	17	18
Mean	26	20	25	15	11	9

blood sugars just described. The mildest diabetic had no glycosuria before, during, or after D.N.P. Glycosurias of the other five patients progressively fell during the period the other five patients progressively fell during the period D.N.P. was given, but only one patient was sugar-free at the end of the course. The mean fall was from 20 g. of glucose in the 24 hours immediately before D.N.P. to 11 g. at the end of the D.N.P. course. Again the hypothesis that the difference between the mean urinary sugars before and after D.N.P. was zero had to be rejected since p was between 0.02 and 0.01 by t -test. The reduction of glycosuria from D.N.P. was significant.

* Consecutive course of D.N.P. and aspirin given.

Oral Glucose Tolerance.—The blood-sugar values immediately before and at half-hour intervals for two hours after an oral dose of 50 g. of glucose are presented in Table IV. The only difference before and after the course of D.N.P. was that glucose tolerance improved a little in two of the six patients: improvement was slight in one and moderate in the other. In the other four patients there was no noteworthy change.

Body Weight.—The weights of the patients before, at the end of the D.N.P. course, and five days after it had been discontinued are shown in Table V. The weights before D.N.P. were steady. Three patients lost 1.3 to 2.1 kg. in

TABLE V.—D.N.P. and Body Weight

Case No.	Body Weight (kg.)		
	Before D.N.P.	End of D.N.P. Course	Five Days After D.N.P.

2	78.0	75.9	75.5
3	79.4	77.5	77.4
4	67.4	67.8	67.6
5	55.1	55.0	54.8
6	42.9	42.2	42.0
Mean	63.3	62.3	62.3

the 14 days D.N.P. was given. The weights of the other three were not materially altered. In the five days immediately after D.N.P. there was no significant change, so that, unlike salicylate, discontinuation of D.N.P. is not followed by diuresis and slight weight loss (Reid *et al.*, 1957). No serious weight changes resulted or followed the 14-days course of D.N.P.: the mean weight loss was 1 kg.

The results so far presented suggest that D.N.P. lowers fasting blood sugar, diminishes glycosuria, and may or may not improve oral glucose tolerance without materially altering body weight. In all these respects it resembles salicylate except that salicylate is much more potent and effective. Nevertheless the qualitative similarity has made it necessary to compare D.N.P. and aspirin. Firstly, the effects on fasting blood sugar and oral glucose tolerance of both substances, given consecutively to four patients in the present study, was examined, and, secondly, the changes in fasting blood sugar in the present group of six patients receiving D.N.P. has been compared with those of a previous group treated with aspirin.

Comparison between Aspirin and D.N.P.

Four of the patients given a 14-days course of D.N.P. were treated with aspirin for a similar period. A short interval of a few days elapsed between stopping D.N.P. and starting aspirin, to allow the D.N.P. to be cleared from the body. This was judged by its disappearance from the plasma or by a fall in plasma concentration to a low value. Comparison between D.N.P. and aspirin on fasting blood sugar and on oral glucose tolerance was undertaken. Measurement of urinary sugar was not considered necessary because it followed the blood-sugar changes induced by D.N.P. and aspirin and also because of the difficulty of making proper allowance for the non-glucose reducing substance which appears in the urine during intensive salicylate therapy.

Table VI compares the effect of both drugs on fasting blood sugar; it will be seen that the mean value, 272 mg. per 100 ml. just before D.N.P. fell to 211 mg. per 100 ml.

TABLE VI.—Comparison of Consecutive Courses of D.N.P. and Aspirin

Case No.	Fasting Blood Sugar (mg./100 ml.)							
	Before D.N.P.				Before Aspirin			
	Days 0-1	Days 3-4	Days 7-8	Days 13-14	Days 0-1	Days 3-4	Days 7-8	Days 13-14
2	228	212	202	196	185	104	104	90
4	304	214	222	204	185	115	143	101
5	293	293	289	252	278	268	138	109
6	262	241	211	190	189	127	118	95
Mean..	272	240	231	211	209	154	126	99

after the 14 days' course. The mean fasting blood sugar just before aspirin was 209 mg. per 100 ml. and this fell to 99 mg. per 100 ml. after 14 days' therapy. The fall with aspirin was greater and more rapid than with D.N.P., though the pre-treatment level was lower. When the t-test was applied to the fasting blood sugar before and after D.N.P. the hypothesis that the difference between the means was zero had to be rejected because *p* was between 0.05 and 0.02. The same hypothesis had to be rejected before and after aspirin, since *p* was between 0.02 and 0.01.

Oral glucose tolerances with a test dose of 50 g. of glucose were carried out in three patients before and after D.N.P. and then after a consecutive course of aspirin (Table IV). Slight improvement in glucose tolerance was noted in one patient after D.N.P. All three showed pronounced improvement from aspirin, which just fell short of a normal response in two.

These findings indicate that, while consecutive courses of D.N.P. and aspirin both reduce fasting blood sugar, the main difference between them is that the reduction from aspirin is more rapid and complete in that fasting blood sugar returned to normal in all four patients. It did not even approach the normal value in any of the four patients treated with D.N.P. This qualitative similarity but quantitative difference in favour of aspirin was emphasized by the results of the oral glucose-tolerance tests.

The increases in oxygen consumption expressed as basal metabolic rates from the third to fourteenth days during consecutive courses of aspirin and D.N.P. to the same patients have been examined in relation to changes in fasting blood sugar. The results presented in the scatter diagram (Fig. 2) emphasize the difference in potency

FIG. 2.—Relation between oxygen consumption expressed as B.M.R. and fasting blood sugar during consecutive courses of D.N.P. and aspirin to four diabetic patients is shown. D.N.P. (open circles) is associated with abnormally high fasting blood sugars; aspirin (solid dots) with normal values for the same increase in oxygen consumption.

increased oxygen consumption in diabetes mellitus from D.N.P. does not reduce the high fasting blood sugar of the diabetic below a certain level, while a similar increase in oxygen consumption from aspirin brings it right down to normal. In both cases the increase in oxygen consumption was as great as would be tolerated in practical therapy.

The superiority of aspirin over D.N.P. in lowering fasting blood sugar may in part be due to the advantage of lower initial fasting blood sugars, since aspirin therapy always followed D.N.P. The importance of this factor has been examined by comparing fasting blood sugars of two groups of six patients treated with D.N.P. or aspirin. One group comprised the six patients in the present investigation who received D.N.P.; the other group was treated with aspirin, and their particulars have already been published (Reid *et al.*, 1957). The patients were all mild to moderately severe diabetics, and on clinical assessment they were comparable. The mean fasting blood sugar just before D.N.P. was 245 mg. per 100 ml.; that before aspirin was 190 mg. per 100 ml. The difference between these means is not significant, since the t-test gave a value of *p* greater than 0.05 and a preliminary F test indicated that *p* was more than 0.05. This is consistent with the suggestion that the two groups were clinically comparable before the treatments. The higher value of the mean fasting blood sugar in the D.N.P. group is at least partly accounted for by the greater mean carbohydrate intake of this group over the aspirin group. The actual figures were 150 g. and 130 g. per day respectively.

The mean fasting blood sugars fell during treatment with D.N.P. and aspirin. The fall in the aspirin group, from 190 to 92 mg. per 100 ml. in 14 days, was greater than that in the D.N.P. group, which was from 245 to 186 mg. per 100 ml. in the same period. Aspirin's obvious superiority was borne out by the values of *p* when t-tests were applied to fasting blood sugar before and after D.N.P. and aspirin. The hypothesis that the difference between the means before and after the two treatments was zero had to be rejected. The value of *p* in the D.N.P. group was between 0.05 and 0.02; in the aspirin group it was less than 0.001.

Discussion

The fall in fasting blood sugar and the reduction in glycosuria from D.N.P. were not expected. MacBryde and Taussig (1935) reported a slight rise in fasting blood sugar and lowered glucose tolerance in two pre-diabetics and one frank diabetic who were given similar doses of D.N.P. The discrepancy between their findings and ours may be more apparent than real, since one patient in our group, comparable to their pre-diabetics, also showed a slight increase in fasting blood sugar after D.N.P. (Table II). It may be that the milder the diabetes the less likely is the blood sugar to fall, for we have observed that rheumatic patients while receiving full doses of salicylate may show a rise in fasting blood sugar associated with diminished glucose tolerance (Cochran, Watson, and Reid, 1950). Indeed, the action of salicylate in diabetes could not have been predicted from its effect in the non-diabetic, emphasizing once again the danger of premature generalization from incomplete data. No subject is richer in examples of this than the literature on salicylate, where it is almost impossible to make a new discovery, but where so much has still to be correctly interpreted.

The similarity in biological effects between salicylate and D.N.P. is most remarkable. Both increase oxygen consumption of cells and mitochondria, and at the same time reduce uptake of inorganic phosphate (Loomis and Lipmann, 1948; Brody, 1956). This inhibition of oxidative phosphorylation is, in biochemical terms, the basic property shared by them. Sodium salicylate and D.N.P. have the same effect on oxygen uptake by certain tissues with a variety of substrates (Sproull, 1957). Both substances stimulate oxygen consumption in animals to the extent of causing death in hyperpyrexia with high doses (Reid, 1957a). They also inhibit plant growth (Reid, 1957b). In all their similarities over a wide biological field, ranging from wheat coleoptile sections, tissue slices, to whole animals, including man, the effective concentrations remain remarkably constant. The current investigation with diabetes brings out yet another similarity in that both lower fasting blood

sugar and glycosuria, though for the same order of increase in oxygen consumption the effect of D.N.P. is slight compared with that of aspirin, and would in itself have no practical value in the treatment of the disease. This raises the question, Is it enough to say that the fundamental action of both D.N.P. and salicylate is inhibition of oxidative phosphorylation without further specification to account for quantitative differences?

Summary

Salicylate and 2:4-dinitrophenol (D.N.P.) inhibit oxidative phosphorylation. Salicylate also controls moderately severe diabetes mellitus. The effect of D.N.P. in the disease has been investigated.

Increased oxygen consumption from D.N.P. of the same order as is required with aspirin to control moderately severe diabetes lowered fasting blood sugar and glycosuria of six elderly diabetics. The reduction was, however, less than that achieved with aspirin, and would have no practical value in treatment.

This difference between D.N.P. and salicylate in diabetes makes it difficult to account for the action of both substances on the basis of inhibition of oxidative phosphorylation, at least, without further specifications.

My thanks are due to Miss M. McCombie, of the dietetic department of the Western Infirmary, for supervision of the diets, and to the staff of the Unit for invaluable technical assistance.

A CASE OF CONJOINED TWINS

BY

W. STIGGELBOUT, M.D., D.T.M.&H.
 Medical Officer, General Hospital, Kaduna,
 Northern Nigeria

Aird's (1954) remark, that owing to the greater accessibility of large groups of populations in Africa and Asia conjoined twins are seen with increasing frequency, is supported by the birth of the Kano and Port Harcourt twins in Nigeria, the case of the twins in Singapore (Roddie, 1957), and our own case as described below.

Case Report

An African woman, gravida-3, about 25 years of age, was seen in the antenatal clinic of our hospital on May 22. She gave a history of 32 weeks' amenorrhoea. On examination the fundus was felt three fingerbreadths under the ensiform cartilage. There was hydramnios, and two hard parts were felt in the fundus. No foetal heart was heard. Twin pregnancy was suspected, and an x-ray film, taken to confirm the diagnosis, showed two foetuses with the heads *in fundo* and the legs well down in the pelvis. The twins were in perfect apposition. Apart from this abnormal position, the vertebral columns showed a peculiar curve, suggesting that the twins were joined at the level of the sternum, thus not allowing the vertebral columns to assume their normal curvature. A presumptive diagnosis of con-

joined twins, with fairly firm union in the region of the sternum, was made, and the woman was admitted.

The next morning an oblique x-ray film was taken. This view showed the details even better, but no definite union could be diagnosed. Several student-midwives were allowed to examine the patient, and a few hours later she com-

Photograph of the conjoined twins.

plained of lower abdominal pains. Very soon the membranes ruptured and a large quantity of blood-stained liquor amni was drained away. One foot presented at the vulva. Examination *per vaginam* showed that there was full dilatation.

Having read Wilson Roddie's report on a similar case, I decided to follow the same method, and the patient was taken to the theatre, where she was anaesthetized. The remaining three feet were brought down, one of them causing considerable difficulty. Then the four legs were delivered simultaneously. Hardly any traction was used, the only force being firm expression. The bodies now descended parallel to each other without any difficulty. It became obvious that the twins were joined together, for they had one abdominal cavity, with imperfect closure in the lower part. When the scapulae were well visible, the legs and trunks were lifted right forward over the symphysis pubis. The posterior head engaged and came out without difficulty, immediately followed by the anterior head. Both foetuses were dead and showed signs of maceration.

A bilateral episiotomy was repaired with catgut. The puerperium was uneventful.

The twins, both girls, had a total weight of 2,350 g. (5 lb. 4 oz.). There was a single placenta with velamentous insertion of two cords. The distance between the insertion of the two cords was 2 cm. The placenta showed small infarcts.

Anatomy

The two female foetuses were preserved in formol-saline and examined after a few weeks. They were joined from the manubrium sterni to just under the umbilicus. The union at the level of the sternum was cartilaginous.

Dissection showed that each twin had its own lungs. The right lungs showed only two lobes, although there was an indication of a third lobe (partial fissure). It seemed that they had one heart in common, but after opening of the

PIONEER NEUROSURGEON

Selected Writings of Walter E. Dandy. Compiled by Charles E. Troland, M.D., and Frank J. Otenasek, M.D. (Pp. 789+vii; illustrated. £5 12s. 6d.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1957.

Walter Dandy (1886-1946) graduated from the Johns Hopkins Medical School; his ability attracted the attention of Professor Halsted, and he was among those of his year who were selected for training in surgery. It was customary for the first year after graduation to be spent in experimental surgery, and this brought him into contact with Harvey Cushing, who was responsible for introducing this feature. The following year Dandy was selected as hospital resident to Cushing. The next year, 1912, Cushing became professor of surgery at Harvard, while Dandy continued in Baltimore, completing his training in general surgery and gradually confining his attention to neurosurgery. The introduction to his life's work appears to have occurred during the year following graduation, when he shared with others an investigation of the blood supply of the pituitary gland. Also during that year of experimental work he studied the absorption of phenolsulphonphthalein from the pleural and peritoneal cavities. This line of thought led him shortly afterwards to investigate cases of hydrocephalus, and with Blackfan he published papers on hydrocephalus which have become classics.

These and many other writings of Dandy have been selected for republication, dedicated to the memory of "a pioneer and most gifted neurosurgeon." Perusing this volume, one realizes how completely justified is this quotation. His outstanding and perhaps unsurpassed contributions to neurosurgery seem to have been due to originality of thought. This has, broadly speaking, shown itself in two ways: (1) the application of novel methods of diagnosis—for instance, the use of air as a contrast medium in radiology—and the value of dye studies (P.S.P.) in hydrocephalus; and (2) the introduction of brilliant techniques in the craft of surgery. The latter has had great influence in the improvement of neurosurgical operations, and it is likely that many neurosurgeons are unaware of the debt they owe to Walter Dandy. This can now be easily remedied, and they will be fascinated by the scope of these papers and by the freshness of outlook which he brought to various problems. He was, of course, particularly interested in the difficulties presented by vascular lesions of the brain, and one can readily imagine how eagerly Dandy would have grasped the possibilities which have been created by the modern adjuncts of anaesthesia—hypotension and hypothermia. One small criticism of this memorial volume—it is a pity that some of the smaller and less important papers were not omitted in favour of a full list of his publications.

D. W. C. NORTHFIELD.

SHORT TEXTBOOK OF OBSTETRICS

A Modern Practice of Obstetrics. By D. M. Z. Stern, M.A., M.B., B.Ch.(Cantab.), F.R.C.S., F.R.C.O.G., and C. W. F. Burnett, M.D.(Lond.), F.R.C.S., F.R.C.O.G. Second edition. (Pp. 258+ix; illustrated. 45s.) London: Baillière, Tindall and Cox. 1958.

This textbook, now in its second edition, provides the medical student with a concise, well-balanced account of present-day obstetrics. Based on the very wide clinical experience of the authors at the West Middlesex Hospital during the last 22 years, it is essentially a practical book. Theories have been avoided except in so far as they have a direct bearing on practical obstetrics, while details of pure anatomy and physiology have been omitted. Largely because of this the book is of small compass compared with

most undergraduate textbooks, but it must be emphasized that it is in no way a "synopsis." Though it runs to only some 250 pages, the format is unusual—with a larger page than is the custom and the type in double columns. As a result the reader will find that a surprising amount of information is contained within its covers, and it provides a very readable and, for the most part, adequate account of the subject, sufficient for the needs of most qualifying examinations. Indeed, with the ever-widening complexity of modern medicine and the increasing demands made upon medical students, its reasonable size is to be regarded as a welcome feature which will commend the work to many readers.

The authors state in the preface that they have aimed "to write upon the subject from a new aspect" and avoid the common failing whereby unsubstantiated statements "have found their way from the pages of one textbook to those of another." In this they have to a large extent succeeded, and most readers will agree that few, if any, clinical myths have in fact been perpetuated. The style of the text is direct and forthright—always a commendable feature, and particularly in a student's textbook of modest proportions. However, on some controversial topics the authors' opinions, dogmatically expressed, may not meet with general acceptance. For example, their preference for face-to-pubes forceps delivery in persistent occipito-posterior cases, the implication that uterine inertia is common in multiparae, their approval of a laterally placed episiotomy, and their condemnation of all mucus extractors are all matters which will provoke criticism. Because of the omission of the basic sciences the uninitiated student may sometimes be a little bewildered when confronted with a new term without explanation, but this disadvantage is largely offset by an appended glossary of terms. Despite the promise contained in the preface, the balance between common and uncommon conditions is not always well preserved. The sections on normal pregnancy, labour, and the puerperium are adequate for the needs of the undergraduate. Most of the common abnormal conditions too are fully described, and the chapters on some of these complications—for example, that on toxæmia of pregnancy—are particularly good. Yet antepartum haemorrhage—surely an important subject—receives only a brief description and is altogether over-simplified. Surprisingly there is no mention of contraction ring (except as a phenomenon of the third stage). On the other hand, space is given to the mention of some rare conditions such as the Chiari-Frommel syndrome.

This textbook is well written, the production is of a high order, and with its unusual format it is a refreshing break-away from the "traditional" student's handbook. There are numerous line drawings, most of which are clear and explanatory. The book is well documented, and an engaging feature is that each chapter is headed by an appropriate Shakespearean quotation. Pleasing additions are an appendix on "Obstetrical Terms Defined" and another on etymology. Such criticisms as are advanced are not intended to detract from the considerable merits of this book. It is a welcome production and can be recommended to those desiring a short textbook that is "different."

M. P. EMBREY.

DIABETES IN THE YOUNG

Diabetes Mellitus: With Emphasis on Children and Young Adults. By T. S. Danowski, B.A., M.D. (Pp. 510+xxiv; illustrated. £5 8s.) London: Baillière, Tindall and Cox. 1957.

The title of this book suggests a somewhat artificial subdivision of a disease of which the two main types are better differentiated by their clinical manifestations than by the age of the patient; in fact, there is often a marked similarity between diabetes in the very young and the very old. This impression is at once dispelled by the first seven chapters, which deal broadly with the biochemical and hormonal aspects of diabetes, and present a concise and up-to-date account which alone makes the book a valuable

NEW THEORY OF SCHIZOPHRENIA

A New Approach to Schizophrenia. By Julius I. Steinfeld, M.D. (Pp. 159. 21s.) London: Hutchinson Medical Publications. 1958.

The author was director of the American Forest Sanitarium, "an institution noted for its research in schizophrenia," so that his views would seem to deserve careful consideration. He regards schizophrenia as a return to infantile behaviour, to the vegetative state, a state prior to ego development, to a state which is called oral, and agrees with Freud that this regression owes its appearance to two factors—a fixation on some object and the occurrence of frustration which makes the individual return to earlier modes of satisfaction. The author's theory deals with the manner in which this fixation occurs. It is regarded as being due to a hunger trauma occurring within a few hours of birth. This produces a ketosis to which infants, especially the premature, are especially liable. Ketosis at this critical period produces some sort of change in the limbic system, the diencephalon, or the hypothalamus. It is impossible to say where, as the author uses these terms indiscriminately. The precise nature of this change is also vague. At times it is said that the diencephalic compensatory mechanisms are exhausted; at others, that the vegetative mechanisms are overstrained. More psychodynamically, there is an overly high cathexis of the diencephalon or an over-catheted hypothalamic mechanism. Anyhow, whatever it is, it leaves the individual vulnerable, and schizophrenia consists in the reappearance, for reasons not specified, of a disequilibrium between cortical functions and diencephalic regulation.

On the basis of this theory the author makes several suggestions for treatment. The object of treatment is to produce ketonaemia. He regards all the current organic therapies as doing this, and mentions several other equally effective methods—for example, starvation, a protein-fat diet, "effective E.C.T." (by continuing to stimulate at a lower amperage after a regular E.C.T. until a picture of decerebrate rigidity is produced), or the inhalation of acetone. As he says, there is no standard treatment in schizophrenia. Strangely enough, he also finds "serpasil" and "thorazine" of value, though he says that these depress the hypothalamus (already depressed or overstrained).

Such a novel theory needs to be buttressed by solid evidence. In an attempt to provide this the author investigated 134 chronic schizophrenics from the point of view of six factors: (1) early hunger trauma; (2) early digestive difficulties, usually called colic; (3) reappearance of abdominal symptoms before the onset of psychosis; (4) overeating or self-starvation; (5) preference for carbohydrates; and (6) attachment to mother or mother-figures. In 61 of these patients no early life history could be obtained, but of the other 72 (one patient seems to have been mislaid) every one showed all of these six features. This is indeed remarkable, but it is a pity that the author did not have any controls. The author's conclusion is that "we believe we must have convinced the reader of the existence of the early hunger trauma and the relationship of such trauma to the later schizophrenia." At least one reader is not convinced.

A. W. BEARD.

asset to anyone with an interest in the scientific side of the subject. The modern views on the pathways of carbohydrate metabolism, the intermediary metabolism of amino acids and proteins, and the actions of insulin are clearly set out in some 20 pages, while the account of the metabolic effects of the pituitary, adrenal, and thyroid hormones is equally condensed, but quite comprehensible. The view that in man total pancreatectomy produces mild diabetes is based on insulin requirement, which is an unreliable criterion of severity.

Part II deals with the manifestations, diagnosis, and therapy of juvenile diabetes, and, under the heading of mortality, surprisingly attributes many of the deaths to coma without, however, specifying whether it is diabetic or hypoglycaemic. The author's attitude towards the aims and objects of treatment is thoroughly sane and realistic, but in the description of treatment itself it is difficult in places to distinguish between theory and practice.

The third and last part is devoted to developmental aspects and complications, including diabetic coma. The dosage of insulin advocated seems to be unnecessarily large, but the danger of hypoglycaemia is reduced by frequent blood-sugar estimations. The statement that "virtually no patient escapes retinopathy after twenty-five or more years of diabetes irrespective of its severity" is not supported by our experience in Great Britain, and would seem to be unduly pessimistic.

There is so much in this book which is vital to the understanding of diabetes, and so relatively little that applies only to children and young adults, that one wishes that the author had allowed himself to cover the whole field. This is a book for the specialist, but much of it, especially Part I, should appeal to all physicians interested in metabolism and endocrinology.

WILFRID OAKLEY.

VIRUS DISEASES

Textbook of Virology for Students and Practitioners of Medicine. By A. J. Rhodes, M.D., F.R.C.P.(Edin.), F.R.S.C., and C. E. van Rooyen, M.D., D.Sc.(Edin.), M.R.C.P.(Lond.), F.R.C.P.(C.). Third edition. (Pp. 642+xv; illustrated, 80s.) London: Baillière, Tindall and Cox. 1958.

In this new edition of their textbook Professors Rhodes and van Rooyen have kept pace with the rapid advances in knowledge of virus diseases. The general layout remains unchanged: there is a comprehensive general introduction on the nature and properties of viruses and the methods of laboratory study, followed by a description of the virus diseases of man arranged primarily on clinical grounds. The text is generously illustrated, and the mass of material is presented in a way which makes it acceptable both for continuous reading and for intermittent reference (though some of the lists for further reading are curiously selected). In the section on respiratory diseases there is a valuable account of the epidemiological behaviour of influenza in the light of current knowledge about the emergence of new strains; it takes the reader just up to the appearance of Asian influenza in 1957. The authors have introduced a full chapter on the diseases caused by adenoviruses, and there is a valuable review of the causes of so-called virus meningitis. This includes the newly discovered enteric or ECHO viruses and a comprehensive account of the Coxsackie viruses. The comprehensive section on poliomyelitis will be particularly welcome from such an authoritative source. Besides a full discussion of modern views on pathogenesis and immunity in poliomyelitis, it includes a description of the Salk vaccine and the results of its use up to 1957. The authors have stressed the great change brought about by the widespread introduction of tissue culture into laboratory diagnosis of virus diseases, and without going into great detail have outlined the techniques which are now available. It is to be hoped that this textbook will help to dispel some of the mystery with which virus diseases are commonly regarded.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 20 1958

FUTURE OF ASIAN INFLUENZA

It is always easier to see a pattern in the behaviour of influenza when looking backwards than when peering into the future. He would therefore be a rash man who would stake his reputation on his ability to forecast the behaviour of influenza in the coming winter. But it is possible to weigh up the probabilities and tempting to make some guesses.

Asian influenza has recently been reviewed at a meeting of experts in Stockholm under the aegis of the World Health Organization, and there was no dispute among them that the Asian virus, or influenza virus A2 as it may come to be called, showed a greater antigenic deviation from previously current strains than has been observed during the twenty-five years since laboratory study of the virus became possible. Because of its great antigenic novelty, and not because of any other advantage over other strains, the Asian virus "put a girdle round the earth" within six months. It found virtually no specific resistance, except possibly in some old people, and in consequence the morbidity was high in many countries. Now the situation is different. Populations have had experience of Asian flu; they will be encountering a familiar enemy. The situation should be much as in other years.

Two factors, however, urge a little caution. Nowhere, over large sections of a population, was the attack rate of Asian flu higher than about 50%. Different countries have given different reports on whether much subclinical immunization occurred. Where two waves occurred in 1957, as in Japan, victims of the first wave were usually spared in the second; so those who suffered last year may be regarded as having a good chance of escaping in this coming winter. But there may well remain some 50% of fully susceptible people among us. This need not make us too gloomy, for it is a well-known principle of epidemiology that a fair proportion of immunes will effectively damp down the spread of an infection. We can thus reasonably expect that an outbreak, if it comes, will be much less extensive than

¹ Mulder, J., *Lancet*, 1957, 2, 334

a year ago. The second factor to consider is the possibility, suggested by J. Mulder on serological evidence,¹ that the Asian flu may represent a recurrence of the epidemic strain of 1889. And this outbreak was followed by second and third waves in the following year or so, each rather worse than its predecessor. Anyone who revels in despondency may dwell on this unhappy precedent, but there are at present no indications of any important changes in the virus, though these must be carefully watched for. We may take comfort from the fact that, though the Asian virus seems to be persisting in more than one country, no serious outbreaks have been reported during the southern hemisphere winter from Australia, South Africa, or elsewhere.

Past experience has shown that, with the appearance of antigenically novel strains, earlier ones seem to disappear. Isolations of A viruses since the Asian one appeared in the spring of 1957 have been almost entirely of this new type. We may therefore expect that viruses closely related to the Asian will dominate the scene, perhaps for a decade. In any case the attack of influenza is usually much the same from the patient's point of view. Many doctors will be asked about vaccination. Last year's experience showed that a vaccine made against the current strain and given in time generally diminished incidence by about two-thirds. The chances of catching flu are presumably less than last winter; it is therefore a matter for personal choice rather than for a country-wide campaign whether, this coming winter, it is worth a needle prick to reduce to one-third the chances of catching a tiresome disease which may never turn up.

EMOTIONS AND MINERS' NYSTAGMUS

Miners' nystagmus, now on the decline, is an interesting example of a psychosomatic disease, and its cause is debated afresh from time to time.¹⁻⁴ The question has again been raised whether it originates primarily in men of emotional instability,⁵ or whether its psychological symptoms are the outcome of an organic disturbance in ocular function—that is, of the continuous rotary oscillations.⁴

The psychological aspect of the disease has been accentuated by the inclusion, under the terms of certification, of patients with active oscillations but with secondary signs of blepharospasm and photophobia, for these are signs common also to other forms of psychoneurosis. To the undiscerning examiner the terms of certification in fact allow the inclusion of patients with poor visual acuity whose complaint of

blurred vision and headache may be due solely to errors of refraction.⁶

The oscillations can be produced experimentally in animals⁷ by prolonged exposure to darkness, and in man are due to working over a long period in a level of illumination which is below the foveal threshold.^{8,9} Not all miners or experimental animals are affected by these conditions, but the incidence of new cases of miners' nystagmus has certainly decreased since the introduction of better illumination in the mines.

The subjective effect of rotary oscillations is to cause a continuous movement of everything which is seen, and this is accentuated when the miner emerges into daylight. He cannot go out into the streets after dark and is often obliged to sit in a dark room at home. He is thus cut off from the society of his family and of his friends. His final breakdown is often preceded by a long period of partial absenteeism. This state of affairs is in marked contrast to congenital nystagmus, in which objects do not appear to move; in these cases it is rare to find psychoneurosis or a failure to continue in employment. It can well be imagined that a moving world can seriously disturb the emotional and physical stability of the miner, in spite of the fact that he develops certain defensive mechanisms by which he can steady his eyes.

In the earliest stage of the disease visual fixation is unsteady. This may be followed by uniocular nystagmus in either a vertical or a horizontal plane. Rotary oscillations begin in the upward gaze, and the eyes can be steadied by a backward tilt of the head, a posture which was at first attributed to photophobia. When oscillations spread to the horizontal gaze, they can again be controlled by "locking" the eyes in a position of lateral deviation, and this is accompanied by the posture so characteristic of miners' nystagmus—namely, lateral rotation of the head and body and a crab-like walk. In the late stages some miners develop generalized tremors while managing to keep the head and eyes still, or their oscillations become so uncontrollable that work is no longer possible.⁶

Since oscillations in themselves give rise to a grave disability, it is desirable that any comparison of the physical and psychological aspects of miners' nystagmus should be made on cases which show active oscillations. This unfortunately has seldom been done. The establishment of the disease as a psychosomatic disorder was based on an analysis of certified cases of all types,¹ some of which conformed to the grouping of hysteria, anxiety, and obsessional states. It was observed that miners could continue to work underground with oscillations unless fear supervened,¹⁰ and conversely that the disappearance of oscillations could culminate in the development of psychoneurosis. There is evidence that anxiety concerning the hazards of underground work will precipitate a breakdown, but a high percentage of normal colliers who were examined at the same time as those with oscillations also showed evidence of emotional stress.⁴ It would thus appear that the dangers of the occupation are also significant.¹¹

The recent application of standardized tests of emotional stability has shown that men with nystagmus are more emotionally unstable than men without the disease.⁵ They gave a significantly higher number of neurotic responses to Heron's test¹² (consisting of a questionnaire as to physical health) and to Wallen's test¹³ (of food aversions), and to Eysenck's tests¹⁴ (of hand and leg persistence). No relationship was found between the emotional stability revealed by these tests and the severity or duration of the disease.⁵ Unfortunately, no criteria of the severity of the disease were given, and no information on whether oscillations or tremors were present, though the latter might well affect the ability to maintain a hand grip or to hold a leg fully extended as required by Eysenck's tests.

The mining industry is notoriously affected by economic conditions, but it is now generally agreed that unemployment is not a contributory factor to the incidence of new cases of miners' nystagmus,¹⁵ though it may play its part in the development of neurosis in long-standing cases. In the years 1930-3, when there was a steep rise in unemployment among miners, the number of certifications for nystagmus actually fell from 41.5 to 25.0 per 1,000 men underground. Conversely they rose by 110% in the war years 1939-43, when unemployment was virtually nil and wages were good, but the stress of work was such that absenteeism, injuries, and deaths rose alarmingly and coal production fell.

If emotional instability is the basic cause of miners' nystagmus, then it is difficult to understand why it does not usually develop before the age of 40, or until 25-30 years have been spent underground. The

presence or absence of oscillations cannot be regarded as unimportant. It has been suggested that they are a stage in the hysterical conversion of symptoms,¹¹ but J. Ohm,^{16 17} who has spent a lifetime in the observation of the disease, has presented evidence that nystagmus is due to a disturbance of the ocular sensory-motor impulses in which the physiological rate of frequency is converted to a pathological one of lower rate. The disturbance is undoubtedly cortical, since it affects integrated movements.¹¹ Whatever the nature of the balance between organic and psychological factors, ophthalmologists at least would still uphold the recommendation made by the Special Committee appointed by the B.M.A. in 1936¹⁸ that "cases should not be certified as miners' nystagmus unless definite oscillation of the eyes can be detected," since any nervous symptom or neurosis exhibited by a miner suffering from nystagmus presents nothing peculiar to his calling, "but has the ordinary features of an anxiety or other neurosis due to other causes."

SURGERY IN PARKINSONISM

The story of the surgery of Parkinsonism begins with the work of R. Meyers,^{1 2} who tried several operative procedures on the basal ganglia and found that section of the efferent fibres of the globus pallidus gave most benefit. He divided these fibres (the ansa lenticularis and the fasciculus lenticularis) through the lateral wall of the third ventricle. The operation was based on the assumption that the globus pallidus is in a state of degeneration in Parkinsonism, though this is now disputed.³ Of twenty-two cases, Meyers obtained much improvement in eight; they were free of tremor but still had some rigidity. In ten cases improvement was not so great; a further two were not improved; and two patients died. Meyers has recently been successful in abolishing tremor and rigidity contralaterally in three patients by subjecting the ansa lenticularis and the fasciculus lenticularis to multibeam ultrasonic waves. Good results are also claimed with other methods of destroying these fibres.⁴⁻⁷

While attempting section of the lateral two-thirds of one cerebral peduncle for contralateral tremor as described by A. E. Walker,⁸ I. S. Cooper⁹ inadvertently damaged the anterior choroidal artery and was obliged to coagulate it. (The anterior choroidal artery arises from the internal carotid just above the posterior communicating artery and is adjacent to the cerebral peduncle.) The pedunculotomy was then abandoned, but the patient was found to be free from tremor on the opposite side and no

abnormal neurological signs were produced. As a result of this experience Cooper continued to coagulate the anterior choroidal artery for Parkinson's disease. The beneficial effects of this operation are due to infarction of the globus pallidus, as experiments on chimpanzees have shown.¹⁰ This operation has a 10% mortality, and it sometimes causes a contralateral hemiplegia and other serious neurological disturbances. It has therefore been given up in favour of less risky methods of destroying the globus pallidus, such as injection of procaine in oil¹¹ and injection of alcohol.¹² The most favoured method is injection of alcohol and is termed chemopallidectomy. It is carried out through a burr-hole, and orientation is obtained by means of pneumoencephalography. The mortality in a series of 245 cases was 2.8%; post-operative hemiplegia occurred in 2%; relief of contralateral tremor and rigidity was obtained in 70%.¹³

Victor Horsley¹⁴ showed in 1909 that removal of the precentral gyrus, area 4 of Brodmann, abolishes contralateral athetosis, and a few years ago P. C. Bucy^{15 16} confirmed this and also succeeded in eliminating tremor by the same procedure, but the involuntary movements are abolished at the expense of spastic paralysis of the affected limbs.

One of the patients whose record appears in James Parkinson's monograph¹⁷ had a cerebral haemorrhage and immediately lost the tremor on the hemiplegic side. This fact, together with the observation that section of the pyramidal tract in monkeys causes little or no lasting disability, led T. J. Putnam^{18 19} to divide the crossed pyramidal tract unilaterally at the second cervical level for unilateral tremor. There was reduction of tremor in 15 out of 22 patients, and most of the patients made a complete recovery from the post-operative hemiplegia. After this operation complete relief of tremor is not obtained and it tends to return to its former amplitude.^{20 21} L. C. Oliver has shown

that unilateral tremor can be entirely eliminated by complete section of lateral column of the cervical part of the spinal cord.^{21 22} Operations on any part of the pyramidal system are best performed only on patients who have had hemiparkinsonism for at least five years without the slightest evidence of involvement of the other side. The price of eliminating tremor by section of a lateral column is some permanent hemiparesis and contralateral analgesia as well as loss of temperature sensation extending up to a variable level but usually reaching the inner border of the arm. Out of 20 patients, 18 were entirely relieved of tremor and 2 were only partially relieved. Other surgeons have obtained comparable results.^{23 24}

Chemopallidectomy is the most promising advance in the treatment of Parkinsonism and is the most generally applicable procedure.²⁵ It can be used in unilateral or bilateral disease. It has a more lasting beneficial effect on rigidity and motor function than on tremor. In long-standing unilateral Parkinsonism in which tremor is the presenting symptom, either because it is embarrassing to the patient or because it is sufficiently severe to interfere with function, section of a lateral column is the more effective operation. But unilateral pallidectomy is worth trying first in such cases, for the patient may be satisfied with this, and damage to the pyramidal system is usually avoided.

ENTEROVIRUSES AND DIARRHOEA

There are now about fifty serologically distinct viruses grouped together as enteroviruses.¹ They include polioviruses, Coxsackie viruses, and ECHO viruses. The enteric cytopathogenic human orphan (ECHO) viruses were so named because they were found by inoculating human faeces into tissue cultures and were "orphans" in the sense that they were "in search of diseases," since most of them were first found in the faeces of normal children. We have recently reviewed² the evidence that some serotypes (4, 6, and 9) apparently cause the aseptic meningitis syndrome. It now appears that some of these orphans may have other "homes." M. Ramos-Alvarez,³ working in Cincinnati in 1955, noted that far more children with summer diarrhoea were excreting ECHO viruses than might have been expected from earlier studies on healthy children. In June, July, and August, 1956, in collaboration with A. B. Sabin, this finding was followed up by studying in detail 97 children admitted to or attending hospital for acute diarrhoea (often associated with fever, vomiting, and dehydration) and 100 other children attending the hospital at the same time but not for "acute illness." About 75% were under 1 year of age. Rectal swabs were collected and examined for the presence of poliomyelitis viruses, Cox-

sackie viruses, and ECHO viruses and for enteric bacteria. The results of both investigations have now been reported in full.⁴ The main points of aetiological importance which emerged seem to be the following. ECHO viruses were isolated in 1956 from 31% of the children with diarrhoea and from 5% of the children without it. The serotypes of ECHO virus found were quite different in 1955 and 1956. They included 5 isolations of type 6, which causes aseptic meningitis. Few polioviruses or Coxsackie viruses were found, and the frequency was the same in both groups of children. In most of the 13 children tested, antibody directed against the ECHO virus which was found in their own faeces appeared in the patients' blood stream after the illness. *Salmonella* and *Shigella* were uncommon, but *E. coli* type O.111 B. 4 was found in 19% of children with diarrhoea and in 3% of those without, though the total frequencies of all types of pathogenic *E. coli* were similar in the two clinical groups. On the clinical side it was noted that children infected with viruses but not with pathogenic *E. coli* were dehydrated in 29% of cases and had blood-stained stools in 20%, whereas children infected with pathogenic *E. coli*, with or without viruses, were dehydrated in about 90% of cases and none had blood-stained stools. There were no deaths. On the data presented by Ramos-Alvarez and Sabin a good case can be made for the conclusion that infection of infants and small children with any ECHO virus may produce a mild summer diarrhoea. This is supported by the report⁵ that ECHO virus type 18 was isolated from 15 cases in a circumscribed outbreak of diarrhoea in a unit caring for premature and older infants in New York. Many more controlled studies on this subject are needed.

It is not surprising that ECHO viruses may cause diarrhoea in small children; symptoms from the alimentary tract are common in the minor or prodromal illnesses produced by polioviruses and Coxsackie viruses. It looks as though many different viruses and bacteria, alone or in combination, can cause the summer diarrhoea syndrome. At the moment it is difficult to guess how frequently this illness is produced by ECHO viruses. If they had used faeces instead of rectal swabs, Ramos-Alvarez and Sabin would probably have found more children infected with enteroviruses. If they had made their study earlier or later in the year, they would probably have found enteroviruses much less frequently than they did in summer. In a series (unpublished) of about 30 English children admitted to hospital in the first three months of the year suffering from diarrhoea without an ascertainable bacterial cause, no enteroviruses were isolated from the faeces. In addition, viruses which are apparently not enteroviruses have been shown to cause acute gastro-enteritis. The viruses cannot be isolated

in tissue cultures or other laboratory hosts,⁶ so human volunteers have to be used, and progress is very slow. However, clinical observations and cross-protection tests indicate that at least two strains of virus exist.^{7 8}

Recent work also suggests that some enteroviruses may cause respiratory illnesses in children. A new strain, JV 1 (ECHO type 20), was found in six infants with feverish colds and coughs.⁹ L. Philipson and T. Wesslén¹⁰ have isolated an apparently new virus named U virus (after Upsala, Sweden). This is almost certainly an ECHO virus, and there is evidence that it is able to cause non-diphtheritic-croup and a cold-like illness in children.¹¹

TREATMENT OF PHENYLKETONURIA

An inborn error of metabolism, phenylketonuria is inherited as a simple recessive characteristic, and it commonly runs in families.¹ The central biochemical abnormality appears to be an inability to oxidize phenylalanine to tyrosine because of absence or inactivity of the enzyme phenylalanine hydroxylase normally found in the liver.² While it is not fully understood how the resultant production of abnormal metabolites brings about the various clinical features of phenylketonuria, particularly the severe mental deterioration, it is probable that they are all due ultimately to the deficiency of phenylalanine hydroxylase, which can be formed only by the action of a single normal gene, which these patients lack.¹

As it is impossible to supply the missing enzyme, the only treatment is to try to correct the biochemical abnormalities. The deficiency of tyrosine can be corrected by giving large quantities of it in the diet. Although this darkens the typically ash-blond hair and fair skin of these patients, it has been of no avail against the amentia.¹ An alternative approach is to reduce the very high levels of phenylalanine in the blood and urine by feeding a diet which is low in phenylalanine. As all dietary proteins are rich in phenylalanine, a suitable diet can be prepared only by supplying the bulk of the nitrogen as amino-acids. This is achieved by freeing an acid casein hydrolysate of phenylalanine, tyrosine, and tryptophan by passing it through a column of charcoal. Tyrosine and tryptophan are then added back, along with glucose, vegetable margarine, wheat starch, and various salts and vitamins to supply a synthetic and highly artificial diet which is, none the less, compatible with a normal rate of growth. Such a preparation is now commercially available.

In 1953 H. Bickel and his colleagues³ reported improvement in a child's mental condition on this diet. Other workers have confirmed this finding, although the degree of mental improvement obtained was widely variable.⁴⁻⁶ It would appear that all the features of the disease except the amentia can be reversed in a short period by a diet low in phenylalanine.¹ The degree of improvement in the amentia must depend on various factors. These children are probably not mentally

deficient at birth, but if treatment is long delayed irreversible brain damage will ensue. The degree of biochemical control of the diet has to be adequate. Although L. I. Woolf and colleagues⁴ obtained considerable improvement in three patients by keeping the phenylalanine content of the diet at such a level that phenylpyruvic acid never appeared in the urine, J. D. Blainey and R. Gulliford⁶ preferred to control the intake of phenylalanine by regular estimations of the phenylalanine levels in the plasma by microbiological assay. Apparently the simple ferric chloride test for phenylpyruvic acid in the urine may be negative in the presence of abnormally high levels of phenylalanine in the plasma. The latter workers found that intakes of phenylalanine as low as 15 mg./kg. a day were fully adequate to permit normal growth provided a high intake of carbohydrate was also ensured.

This year L. I. Woolf and his colleagues from Great Ormond Street⁷ have reported the results of treating eleven patients for periods varying from 11 to 34 months. Their patients were submitted to careful psychometry at regular intervals, and the phenylalanine intake was controlled by frequent estimations by paper chromatography of the concentrations of phenylalanine in the blood and urine. They stress that too low an intake of phenylalanine will result in an unsatisfactory rate of growth. The results give clear evidence of the effect of the diet on the mental condition. In most cases there was a sharp rise in mental age as against chronological age as soon as the diet low in phenylalanine was started, and the improvement was maintained while the child stayed on the diet. None the less, in all but two patients the mental age remained well below the mean for the population as a whole. In one of these treatment was started at the age of 5 weeks. The other was atypical in that her intelligence before treatment was unusually high. The overall results indicate that there is an irreversible component in the mental deterioration which appears at a very early age. It seems unfortunately to be the case that by the time phenylpyruvic amentia is established a low-phenylalanine diet is likely to raise a child's mental rating only from idiot to imbecile level, hardly a very gratifying achievement.

If the intelligence is to be preserved, dietary treatment must start before measurable mental deterioration has occurred—that is, before the diagnosis can be suspected by simple observation of the patient. The Great Ormond Street workers recommend that every child's urine should be tested at the age of 21 days by the ferric chloride test. This would require organization on a national scale to detect somewhere between 20 and 40 new cases each year. Certainly the urine of a sib of a known phenylketonuric should be tested frequently during the first 3-4 weeks of life, because the chances that he also will be affected are one in four. It is worth

emphasizing, too, that low-phenylalanine diets can be controlled only in a children's hospital or department with generous laboratory facilities. Unfortunately the difficulties of managing the diet when the patient goes home will inevitably result in some patients being inadequately controlled.

RADIOACTIVE STERILIZATION OF INSECT PESTS

In the past decade new synthetic insecticides have achieved great success in the control and eradication of insect-borne disease, but already their powers are seriously threatened by the emergence of many resistant strains. This intensifies the interest in an entirely new method of attacking insects by liberating large numbers of radioactively sterile individuals. The method depends on the well-known sensitivity of reproductive tissues to radiation. Doses of about 5,000 r (ten times the dose lethal to most mammals) can be given to certain insects in the pupal stage without greatly curtailing their lives; but the resulting adults are generally sterile. The females of many insects allow only a single mating, and if this has been with a sterile male the act is sufficient to prevent reproduction. To eradicate a pest, then, it is necessary to liberate sufficient numbers of sterile males to compete successfully with normal wild ones.¹ That this is sometimes feasible has been shown by American workers who have exterminated the "screw worm" fly (which breeds in wounds and sores of animals) from the island of Curaçao,² which has an area of 170 square miles (440 square kilometres). The flies were reared in vast numbers, sterilized in a cobalt-60 irradiator, and released at the rate of about 400 males per square mile (150 per sq. km.) weekly for about 20 weeks.

Blowflies, like the screw worm, are particularly vulnerable to attack by this means, since their wild populations are naturally small (a few hundred to the square mile). Many pests are much more numerous; and it would seem impossible to produce enough sterile mosquitoes to compete with natural populations estimated at three-quarters of a million per square mile³ mated at three-quarters of a million per square mile (300,000 per sq. km.), or midges, which may reach a figure of 3 million per square mile (1-2 million per sq. km.).⁴ One of the most hopeful possibilities is the tsetse fly (which is normally sparse in nature), and this is being investigated by British workers at the present time.⁵ Certain difficulties arise at once: for example, the long life cycle of the tsetse would require the release over a long period of the sterile males; and, more important, great difficulty attends the breeding in large numbers of tsetse flies in captivity, so that at present wild pupae of unknown age must be collected for irradiation. A further drawback is that female tsetse can mate more than once, though they seldom do so more than twice.

⁵ Potts, W. H., *Proc. roy. Ent. Soc. C.*, 1947, 22, 2 and 9.

The possibilities of radioactive sterilization are being studied with other insect pests as well as tsetse. Success of the method clearly depends on the interaction of many factors, including the ease of sterility without curtailment of life, the frequency of mating of the females, the length of the life cycle, and, above all, the ease of rearing for irradiation numbers large enough in relation to natural populations. Unlike insecticidal control, the method becomes progressively more efficient as the natural populations decline. Perhaps, therefore, it may be most feasible against residual populations, after decimation by intensive insecticide campaigns.

UNITY IN FIRST AID

As our correspondence columns have shown from time to time, opinions on first aid are apt to be expressed with uncommon emphasis. Perhaps this is a reflection of the circumstances in which it is often rendered. Drastic action must be taken quickly, possibly in co-operation with other first-aiders, who may have been taught to apply different methods. To a sense of urgency must be added a facility in recalling almost automatically what the correct procedure is; and the first-aider's exertions may easily make all the difference between life and death. An important advance towards achieving a common practice of first aid has now been taken in the publication of a single, joint manual¹ by the St. John Ambulance Association, the St. Andrew's Ambulance Association, and the British Red Cross Society. Slightly larger than the older manuals, this nevertheless fits the pocket neatly, is easy to read and well illustrated, and is strongly stitched and bound. Expert (though anonymous) contributors have supplied the text, which has been edited by Dr. L. S. Potter, and it naturally reflects modern views on the subject. In the treatment of shock, for instance, hot-water bottles are barred, and the flow of hot, sweet tea is reduced to sips (but in the treatment of "minor burns" this is given in "large quantities"). Pressure points at which to arrest blood flow in the arteries are described and illustrated for the carotid, subclavian, brachial, and femoral arteries. Modesty seems to prevail over clarity in that pressure to the femoral artery is shown being applied through the subject's trousers, though the advantage of illustrating these points with the unclothed body is evident from the neighbouring diagrams. In teaching how to stop bleeding from a varicose vein in the leg the booklet rightly lays emphasis on raising the leg and keeping it raised. All the usual features of first aid are set out—various methods of artificial respiration, bandaging, and carrying casualties—and among the appendices is one on first aid in hot climates. Here the treatment of snake-bite finds its place. But what to do in Great Britain when an adder fastens on the leg that disturbs it is probably one of those parts of first aid that are still open to debate.

BIOCHEMISTRY'S EXPANDING HORIZONS

FOURTH INTERNATIONAL CONGRESS

[FROM A SPECIAL CORRESPONDENT]

Three years have elapsed since the Third International Congress of Biochemistry, in Brussels, which over 3,000 scientists attended. The Fourth International Congress, just finished, took place in Vienna from September 1 to 6, and 6,000 went to it. Over 1,700 papers were received and there were five colloquia and twelve symposia. The subjects considered ranged, to mention but a few, from the carbohydrate chemistry of substances of biological interest, such as the carbohydrates of the nucleic acids, to the biochemistry of the central nervous system, the steroids, antibiotics, morphogenesis, viruses and proteins, blood-clotting factors, and vitamin metabolism. The inevitable overlapping made it impossible to attend all the sessions one would have liked, as at times papers were being read simultaneously in twenty different lecture theatres. Indeed, the choice was often embarrassingly difficult. For example, papers on brain metabolism and the effects of neurotropic agents by Professor J. H. QUASTEL, F.R.S. (Montreal), the modes of action of antibiotics by Dr. F. E. HAHN (Washington, D.C.), and the genetic control of the protein structure of abnormal haemoglobins by Dr. V. M. INGRAM (Cambridge) were read simultaneously.

Chemistry of Heredity

The inaugural session was opened with speeches of welcome by Professor F. BRÜCKE (Vienna), Professor O. LOEWI (New York), and others, and by Professor C. F. CORI (St. Louis), president of the Congress, who emphasized the need to translate biochemical knowledge to practical problems. The inaugural lecture was then given by Professor E. W. CHARGAFF, of New York, on "First Steps Towards a Chemistry of Heredity." In his cautious survey of present knowledge and future hopes Professor Chargaff pointed out that, despite the considerable increase in biochemical knowledge since the time when vitalists fought one another in ignorance and fog, we were still very far from the biochemistry of individuality; while a ladder might by now have been placed towards the heavens, it would be a hundred years before we should have passed the first one or two rungs on it. We had some appreciation of the interrelationships and the biochemistry of heredity of deoxyribonucleic acids (D.N.A.), ribonucleic acids (R.N.A.), proteins, lipids, and polysaccharides, but very many questions had to be answered, among which was whether the D.N.A.s were the genetic carriers.

The Congress then divided into the various symposia and colloquia. The papers reflected a very active period of increased knowledge, although no major advances were recorded. Several of the findings reported in the virus field may pave the way towards further research on virus diseases and eventually, perhaps, to their treatment. It is by now generally accepted that the crucial event in viral infection is the introduction of the viral nucleic acid into the host cell, and a number of papers were concerned with aspects of this phenomenon. In the bacterial field, where considerable evidence has already been gathered in favour of the view that D.N.A. alone is involved in the transmission of hereditary characteristics, Dr. L. M. KOZLOFF (Chicago) described the changes in the tail structure of bacteriophage during invasion, the phage's action on its host's cell wall, and the forces involved in the passage of the viral D.N.A. from the head of the phage particle through its tail into the host cell. He drew attention to recent experiments indicating that there is a contractile protein in the tail of the bacteriophage T2 which plays an important part in all the three phases of the invasion.

Viral Infectivity

Viral infection had also been studied by several other workers using tobacco mosaic virus (T.M.V.). The finding

that it is possible to dissociate a number of viruses, including T.M.V., each into their separate protein coat and nucleic acid component, and to recombine them, has raised the problem of whether the whole of the virus particle, or only a small part of it, is essential for its biological activity. Dr. H. FRAENKEL-CONRAT (Berkeley, U.S.A.), and Drs. J. GIERER (Stockholm) and G. SCRAMM (Tübingen), recorded originally that properly isolated viral nucleic acid alone was able to initiate the infective process and the reproduction of the virus. Its activity was, however, only of the order of 0.1% to 0.5% of that of the original virus; and, though these results were confirmed by other laboratories, the problem remained of why it should not be possible to obtain more highly infective preparations of the isolated T.M.V. nucleic acid. Dr. FRAENKEL-CONRAT thought the explanation might be the great lability of the pure nucleic acid material to various agents—the foremost of which is ribonuclease—which it might encounter on the leaf surface. Dr. B. COMMONER (St. Louis), on the basis of experiments he described, thought we must distinguish between two types of infectivity: inherent and acquired. For inherent activity the presence of an intact or nearly intact R.N.A. (virus R.N.A. and some of the virus protein) chain was essential, any process which broke part of the chain reducing this inherent activity nearly to zero. He put the amount of protein needed at as little as, possibly, a single sub-unit of molecular weight 20,000. How such a single protein sub-unit—which is quite small compared with the entire R.N.A.—could endow the total nucleotide chain with the virus generative configuration was answered by the suggestion that the protein sub-unit might act as a movable templet over which the R.N.A. chain could pass, thereby acquiring a continuous series of repetitive local patterns. Although the structure of the protein was fixed, the configuration of the protein-R.N.A. complex would be expected to vary continuously as a function of the linear sequence of the polynucleotide chain. A crude analogy to this process is what happens on a tape recorder. Acquired infectivity, resulting perhaps from the interaction of host tissue with invading particle, was found only in shortened rods of T.M.V.; and in this case the replication of the virus nucleic acid might be a linear rather than a side-to-side process.

Dr. P. ALEXANDER and Dr. K. A. STACEY (London) reviewed the evidence on the ability of ionizing radiations and certain mutagenic chemicals to modify D.N.A. Treatments which altered its physico-chemical properties had been shown to destroy at the same time its power of transformation. The parallelism between mutagenicity and tumour inhibition might be due to a similarity in mechanism and the difference depend only on the extent of the damage or change in the D.N.A.

Antibiotics against Cancer

Dr. G. F. GAUSE (Moscow) reviewed the biochemical basis of the search for antibiotics against cancer, relating the screening of substances for selective cytostatic or cytotoxic effects on tumour cells to biochemical differences between normal and malignant cells. He compared cancer cells and possibly equivalent mutated micro-organisms, and discussed the use of the latter for screening purposes. He remained cautious, however, on the question of whether chemicals that inhibit the growth of these biochemically mutant micro-organisms would prove of practical importance in the treatment of malignant growth.

The general impression left by the Congress is that the progress reported represents steady, and in places considerable but by no means major, advance. A sobering thought, however, is that the frontiers of biochemical knowledge may soon advance at such a rate as to outstrip man's capacity to correlate the information acquired. At the Third Congress over 500 papers were read, at the present Congress over 1,700. How many papers will be presented at the next one, which, it has just been announced, is to take place in Moscow in 1961?

HEALTH OF THE AGED

Europe's ageing population and the pressing health problems it raises were the subject of debate in two international forums recently: the first an advisory group convened by the European Office of W.H.O., which met in Oslo from July 27 to August 2; and the second the European League for Mental Health, which met in Vienna on August 23.

Forced Retirement

The European League for Mental Health discussed the mental health problems of the older worker and those of retirement. Dr. DORIS ODLUM defined "an older worker" as one who, on account of age, met any special difficulties in obtaining or retaining employment or who on this account was less able to do satisfactory work. While more people of both sexes now lived longer and retained much of their vigour and working capacity until the late sixties or even older, many, she said, even in their fifties or early sixties could not obtain suitable employment, and a number were arbitrarily retired long before their capacity to do efficient work had diminished. This often produced mental distress. Investigation showed that few people gave up work voluntarily merely because they wanted more leisure. In fact, many dreaded the prospect of idleness: they felt discarded and tended to lose their incentive to keep active. This could lead to premature deterioration and early senescence. Older women, because they had their homes and husbands to care for and often other interests as well, tended to suffer less than men. Besides supplying him with money and material advantages, his work was the main means of fulfilling a man's ego. The retired man not only had to diminish his style of living because he had less income but he was not wanted in the home or indeed anywhere, and the greatest enemy to mental health was the feeling of being redundant. In the case of the widowed or unmarried loneliness was often a great problem. Dr. Odlum's proposals for mitigating these situations included the provision of more suitable and more part-time work and the avoidance of compulsory retirement so far as possible. The preparation of a man for his retirement was also vitally important, since his personality and the attitude with which he faced the new situation would largely decide how far he could adapt to it.

Professor PAUL REITER, of Copenhagen, said they had a very similar problem in Denmark, which was rapidly changing from an agricultural to an industrial economy. He described some of the mental and emotional disturbances affecting the older and retired worker seen in his clinic, and said it was now realized that many cases thought previously to be senile psychoses were really psychogenic and could be greatly helped by medical and social care.

Dr. ANDRÉ REPOND, Switzerland, said that the problems of the agricultural communities were considerable and not to be ignored. Their pattern of life was also changing. Dr. VEIL, France, said that preparation for ageing really began in childhood and at school: the lower the standard of education and cultural background, the earlier the decline of mental powers.

W.H.O. Regional Group

The W.H.O. group consisted of experts in various aspects of gerontology and geriatrics from Finland, France, Germany, Italy, Netherlands, Norway, Sweden, U.S.S.R., the United Kingdom, and Yugoslavia under the chairmanship of Dr. JEAN HUET, of Paris. Professor W. HOBSON, of Sheffield University, was the United Kingdom representative. They had the task of surveying the present health needs of the aged in Europe and of framing recommendations for the W.H.O. European Regional Office and for governments. Having cleared the ground by reviewing the demographic trends in different countries and the existing provision for the aged, the group discussed in detail the planning and organization of health and medical services for the elderly.

Education of the public about the problems of the elderly was thought a useful preventive measure for some of their disabilities, but more information was needed on such questions as the value of routine health examinations and multiphasic screening procedures. The group's recommendations will be the subject of a special report.

APPROVED NAMES

"Approved names" are devised or selected by the British Pharmacopoeia Commission, and the intention is that if any of the drugs to which these approved names are applied should eventually be described in the *British Pharmacopoeia* the "approved name" should be its official title.

The previous supplement to the consolidated list of "approved names" was published in the *Journal* of May 17 (p. 1175). A new supplement, dated August, 1958, is printed below. Communications relating to "approved names" should be addressed to the Secretary, British Pharmacopoeia Commission, General Medical Council, 44, Hallam Street, London, W.1.

Approved Name	Chemical and Other Names	Notes
Ambazone	1: 4-Benzoquinone amidino-hydra-zine thiosemicarbazone hydrate "Iversal"	Antiseptic for local treatment of buccopharyngeal infections
Beclamide	N-Benzyl-β-chloropropionamide "Nydrane"	Anticonvulsant
Benztropine	3-Diphenylmethoxytropine "Cogentin" is the methane-sulphonate	Symptomatic relief of Parkinson's syndrome
Bisacodyl	Di-(p-acetoxypheyl)-2-pyridylmethane "Dulcolax"	Laxative
Chlorphenesin	3-p-Chlorophenoxypropane-1: 2-diol	Fungicide
Clemizole	1-p-Chlorobenzyl-2-pyrrolidino-methyl-benzimidazole "Allercu" is the hydrochloride	Antihistamine
Clemizole Penicillin	Benzylpenicillin combined with 1-p-chlorobenzyl-2-pyrrolidino-methyl-benzimidazole "Megacillin"; "neopenyl"	Antihistamine penicillin with prolonged depot action
Deanol	2-Dimethylaminoethanol "Atrol" is the bitartrate	Treatment of schizophrenia and other mental disorders
Dimethisterone	6α: 21-Dimethylethisterone "Secrosteron"	Progestational agent
Ethioheptazine	Ethyl(1-methyl-4-phenylazacycloheptane-4-carboxylate "Zaciane"	Analgesic
Framycetin	An antibiotic derived from <i>Streptomyces decarls</i> "Soframycin" is the sulphate	Treatment of cutaneous infections
Furazolidone	3-(5-Nitrofurfurylideneamino)-oxazolidin-2-one "Furoxone"	Treatment of bacterial diarrhoeas and enteritis
Inproquone	2: 5-Bisethylethimino-3: 6-dipropoxy-1: 4-benzoquinone	Cytostatic agent
Pempidine	1: 2: 2: 6: 6-Pentamethylpiperidine "Perolysen" is the hydrogen tartrate; "tenormal" is the hydrogen tartrate	Treatment of hypertension
Phytomenadione	2-Methyl-3-phytyl-1: 4-naphthoquinone "Vitamin K ₁ "; "konakion"; "mephyton"	Treatment of hypoprothrombinaemia
Piprinhydrinate	Diphenylpyralline salt of 8-chlorotheophylline 4-Diphenylmethoxy-1-methylpiperidine salt of 8-chlorotheophylline "Koltan"; "mepedyl"	Antihistamine
Sulphaethidole	5-p-Aminobenzenesulphonamido-2-ethyl-1: 3: 4-thiadiazole "Sehadil"	Treatment of infections of the respiratory tract
Sulphathiourea	p-Aminobenzenesulphonylthiourea "Badional"	Bacteriostatic
Trimethidinium Methosulphate	(+)-3-(3-Dimethylaminopropyl)-1: 8: 8-trimethyl-3-azabicyclo[3: 2: 1] octane di(methyl methosulphate) "Camphidonium"	Treatment of hypertension

The International Academy of Gynecological Cytology has published the first number of *Acta Cytologica*, which will appear three times a year. Besides reports of the Academy's symposia the *Acta* will print only articles written by invitation. Subscription is \$4.50, and the editorial address is 5841, South Maryland Ave., Chicago 37, U.S.A.

To-day's Drugs

Correspondence

In this column we publish from time to time authoritative notes on a selection of drugs in current use.

Otamidyl (May and Baker Ltd.).—Ear drops containing dibromopropamide isethionate 0.15% and di(p-aminophenyl)amine dihydrochloride 0.5% in propylene glycol. Otamidyl is intended for the treatment of otitis externa and chronic suppurative otitis media. After the meatus is cleaned, the preparation is instilled as drops or inserted into the meatus soaked on ribbon gauze. Application should be carried out once to three times daily, depending on the severity of the infection.

The aromatic diamidine series of drugs, which include the two used in this preparation, are claimed to have an antibacterial action against pyogenic cocci and some of the Gram-negative bacilli, particularly, in adequate concentration of the drugs, *Pseudomonas pyocyanea*, *Proteus vulgaris*, and *Escherichia coli*. The *E. coli* organisms are of importance in chronic ear infection. Di(p-aminophenyl)amine dihydrochloride is active in the presence of pus and tissue debris against those pathogenic fungi which are occasionally found in ear infections. However, fungi are rarely the primary infecting agent in temperate climates, though in the tropics they are occasionally found.

The meatal skin is known to be more readily sensitized to chemicals than other areas, and, while the agents present in otamidyl are probably no more irritant than others in common use, careful supervision is necessary. Application should be discontinued at the first sign of sensitization. If no improvement takes place after one week, other agents should be tried.

N.H.S. basic price: 15 ml. (with dropper), 3s.

Cafdis (Reckitt and Sons Ltd.).—Each tablet contains aspirin, phenacetin, and caffeine in the same dose as in the standard preparation of compound aspirin tablets, *B.P.C.*, with the addition of 63 mg. calcium carbonate and 21 mg. citric acid. This is an elegant foil-wrapped preparation in which the additional components render the constituent aspirin soluble and possibly less irritant. They might well be prescribed as an alternative to *A.P.C.* tablets, *B.P.C.*, if the therapeutic benefit achieved justifies the higher cost.

N.H.S. basic price: 500 tabs., 16s.

ORDER OF ST. JOHN OF JERUSALEM

Those recently appointed to, or promoted in, the Venerable Order of the Hospital of St. John of Jerusalem include the following members of the medical profession:

As Knights: Colonel F. A. Bearn and Mr. H. S. Taylor-Young. *As Commanders (Brothers):* Surgeon Rear-Admirals D. M. Beaton, Q.H.P., and D. F. Walsh, Major-General A. E. Campbell, Q.H.P., Colonels M. MacEwan and G. E. Wight, and Drs. E. C. Brewis and T. W. A. Gray. *As Commander (Sister):* Dr. Elsie C. Hanson. *As Officers (Brothers):* Major-General T. F. M. Woods, Q.H.P., Brigadier C. S. Thompson, Colonel G. Anderton, Lieutenant-Colonel D. H. D. Burbridge, Mr. J. B. Dobson, and Drs. K. H. Blaauw, A. D. Griffith, A. Russell, D. P. Kennedy, J. G. Stewart, T. H. Pullar, J. Moffat, W. A. Hogg, H. J. Hoby, D. S. Napier, L. S. Potter, F. E. Fletcher, J. W. Pickles, C. D. Short, and M. G. Townsend. *As Associate Officer (Brother):* Mr. S. Bloom. *As Officer (Sister):* Dr. (Mrs.) Marguerite F. E. Wylie. *As Serving Brothers:* Colonel K. J. Coates, Lieutenant-Colonel G. S. Michelson, and Drs. C. G. Cassar, A. I. McKendrick, A. G. B. Minn, J. W. Ridley, A. Iredale, T. R. Bryant, J. Griffiths, T. O. Jones, D. E. P. Pritchard, I. N. Anastasiades, D. A. McCracken, J. H. Haldane, R. C. Williams, J. H. Pattison, R. Stanford, R. P. Graham, C. N. Suter, G. W. May, R. Caille, A. N. Coondoo, J. H. Chambers, J. A. C. Burridge, R. Hickey, A. J. Mascari, H. Marshall, B. P. R. Hartley, W. Brown, J. F. Baker, W. M. Farr, J. F. Haszard, E. R. Hicks, A. C. Martin, H. A. Myers, P. E. Vaillancourt, and J. S. Young. *As Associate Serving Sisters:* Drs. S. Gordon and A. Epstein. *As Serving Sister:* Dr. Elizabeth O. N. Armstrong.

Attempted Suicide

SIR.—I read with interest the article by Mrs. Moya Woodside on attempted suicide (*Journal*, August 16, p. 411). The problem presented by the patient who attempts to take his own life is difficult, and to a greater or lesser extent unresolved by all who come into contact with it. By and large the experience of the workers at Guy's would seem to be somewhat general: that the police are very considerate regarding this problem.¹ In many cases the predicament of the accused is due in large measure to the lack of effort made in the general hospital to which the prisoner was first taken: no effort made to admit for investigation, no effort made to organize psychiatric care, and little practical concern for the social welfare of the patient.²

A number of attempted suicides, on remand, that I have occasion to see working in one of H.M. Prisons are without fixed abode, without relatives, and without friends. They are not certifiable under the Lunacy Act, 1890, and support for this contention is that they have not been admitted to an observation ward via the Duly Authorized Officer even, having been first seen in a general hospital. Further, these prisoners either will not accept the offer of voluntary admission to a mental hospital under the Criminal Justice Act, 1948, Sec. 4, or the appropriate mental hospital for their catchment area will not agree to their admission. What can, and what should, be done under these circumstances?

If one accepts (as I do) the remark made by Mrs. Woodside that an unsuccessful suicide may represent "a desperate and final appeal for help," often unconscious, then some action must be taken. Stengel and Cook³ make a similar statement that the appeal to society is "inherent in most suicidal attempts irrespective of the mental state and the personality of the person." Faced with answering this *cri de cœur* from the unconscious, either admission to hospital as a voluntary or certified patient, or the recommendation of probation with or without a condition of out-patient psychiatric treatment, is arranged whenever possible. When, however, one is presented with a prisoner not certifiable but not "well" enough to be placed on probation (still a suicidal risk) who refuses voluntary admission, or is refused such admission, then I submit he should properly be sentenced to imprisonment and that where possible he should receive treatment within that setting. The sentence passed should be sufficiently long to allow of there being time for adequate treatment to be instituted. I am not advocating a long sentence for a suicidal attempt on purely punitive grounds. Further, I would add that the remarks of Chapman that are footnoted by Williams in his book⁴ are not to be taken seriously to-day, whether or not they were true when first written some 26 years ago. What I have so far stated is applicable only to those prisoners who are "treatable" as assessed by fairly general criteria. What of those who cannot be so described? Without being apologist for the present law, the words of Williams⁵ are again convenient, "... people are never sent to prison for attempted suicide except in the fullness of Christian love." East⁶ would also see in a period of institutionalization (imprisonment) real value and pay tribute to rest, good food, quiet, and medical attention as an opportunity "to recover their normal emotional level."

Thus far I have written in terms of the present law, the policy of the majority of the Benches and mental hospitals accepting that one has a duty to answer the symbolic appeal in the attempted suicide. Changes that I would like to see would be more medical appraisal on bail, with, if necessary, a condition of residence in a hospital. This would be very much better than spending one, two, or three weeks in prison. There is no reason why, at the present time, these persons could not be reported on whilst on bail, but the

possible explanation of why outside clinics are so little used by the Benches has been set out by Scott.⁷ There is little doubt, however, that most people to-day feel that attempted suicide (and successful suicide) should be outside the province of the criminal law. That they should not be regarded as criminals but, as Larremore⁸ has suggested, unfortunate persons who might possibly benefit from a temporary deprivation of liberty. Other similar proposals have been made.⁹ Again, as Williams⁵ states, "... there would be no need for the hearing by the magistrates to take place in public ..." and thus no need for press reporting or an order to be made unless specially needed. Further, "A very short time limit should be placed on the detention order. ... Ultimately society cannot stop a free man from committing suicide, nor should it try. What can be done is to make sure that the determination upon self-destruction is fixed and unalterable."

I would accept this myself, but would make the plea that at present in an endeavour to treat the patient, or make certain that the resolve of self-destruction was truly fixed, the psychotherapeutic units within the prison framework have a very real part to play in the case of a number of prisoners. In other words, simply taking the act of attempted suicide outside the criminal law would not be of great benefit unless some agency were created to fill the gap that would be left in the case of a number of patients.

I must point out that the views expressed in this letter are my own and do not necessarily represent the opinion of the Prison Commissioners.—I am, etc.,

London, S.W.2.

Beds for the Aged

SIR.—In his letter (*Journal*, August 30, p. 567) Dr. W. H. Lloyd rightly stresses the importance of better use of existing hospital beds, and the need for adequate nursing, medical, and ancillary staff, if the problem of hospital accommodation for the aged is to be solved. Some facts to show what was achieved by the late Dr. O. Olbrich in Sunderland may be an encouragement to others to adopt a more "active" approach to the problem.

During the years 1950 to 1957 Dr. Olbrich was able to transform a department consisting of 571 beds for the chronic sick, with a long waiting-list for admission, into an active medical department with no waiting-list. During this time the number of admissions increased from just over 500 to over 3,300 a year, and the average days of stay of a patient have diminished from over 2½ years to 28 days. In addition, 74 beds were given up as redundant. Quick reference to the weekly cost of this type of bed in any area will show that the closure of this number of beds results in the saving of well over £40,000 a year.

To save money on medical and nursing staff and equipment is false economy, as it results in inefficient use of beds, which is inherently more expensive per patient. Rehabilitation must begin with diagnosis. If any area wishes to transform a hospital for the chronic sick into an active geriatric unit, the first essential is to appoint a consultant geriatrician, who has had at least two fully trained in general medicine, who has had at least two years' experience in an efficient and active geriatric department. He may then be supported fully in his requirements for staff and equipment, with confidence that the money so spent will be recovered by reduction in the number of beds required, or where the original number of beds is grossly inadequate by the provision of a greatly improved service.—I am, etc.,

Sunderland.

ELUNED WOODFORD-WILLIAMS.

Test for Completeness of Vagal Section

SIR.—Burge and Vane¹ described a test for completeness of nerve section which could be used during the operation of vagotomy in the treatment of duodenal ulceration. Prior to this the only means of assessing completeness was the insulin test meal carried out post-operatively. It is clear that incomplete nerve section may lead to recurrent ulceration. There is evidence that in the past vagotomy has carried a high incidence of incompleteness as judged by the insulin test.^{2,3} If we conclude that section of all nerve trunks is desirable it follows that the use of a test during operation is essential.

We have found, and all surgeons who saw the test agreed, that the original method needed simplification. Filling, emptying, and refilling the stomach with water from a large reservoir was unsatisfactory for routine theatre use. We now use air in place of water for gastric distension, and a simple manometer for pressure measurement. In cats, comparing the sensitivity of air and water methods, we found that the amplitude of gastric contractions on vagal nerve stimulation is only slightly less with air. Fig. 1 shows kymograph tracings of gastric pressure responses to stimulation of the right cervical vagus nerve in a cat. Responses of the water-distended stomach (upper trace) are compared with those obtained using an equivalent volume of air (lower trace): stimulus applied for 1½ mins. It is fortunate that good responses are obtained over a wide range of gastric filling.

Our experience has been that the human stomach behaves in a similar way. Fig. 2 shows tracings of the gastric pressure response to stimulating a single vagal nerve trunk in man with different volumes of air in the stomach (stimulus applied for 1½ mins.). The optimum volume of air to be introduced is difficult to assess because of individual variation in stomach size. In practice we find the intragastric pressure a reliable guide, and we are well within the range of satisfactory response when this is between 15 and 20 cm., measured on the water manometer. The volume required to achieve this may vary from 500 to 1,200 c.c., and in the partially resected stomach may be as little as 200 c.c. At no time should the stomach wall feel tense.

The details of premedication and anaesthesia are as described in the original paper. We have incorporated muslin in the latex of the cuff on the stomach tube, a factor designed to prevent overdistension. The 5-inch (12.5 cm.) bag is filled with water rather than with air and stimulation details are as before. Fig. 3 shows the stomach tube connected to a water manometer (E), and by means of a side-arm air is introduced with a sphygmomanometer bulb (D). The

FIG. 1

FIG. 2

FIG. 3

electrode (A) is placed round the lower oesophagus. The stomach is occluded at the pylorus by clamp (B), and the cuff of the gastric tube (C) inflated. The stomach is distended with air by the bulb (D) until a pressure of 15 to 20 cm. is recorded on the water manometer. The responses of the stomach to stimulation are measured on the manometer and noted. This is less satisfactory than a continuous written record, but it is inexpensive and virtually infallible, thereby differing in our experience from mechanical recording systems. The method has been tested in intact and partially resected stomachs. We are satisfied that this test is safe and reliable. With these modifications it is now well suited for general surgical use.

We wish to thank the Dan Mason Research Foundation of the West London Hospital Medical School for financial help in this work. We thank Wm. Warne & Co. for making the gastric tube, and Mr. D. Green for constructing the manometer.—We are, etc.,

London.

Excision of Atrial Myxoma

SIR,—The method of removal described by Mr. L. Fatti and Dr. F. P. Reid (*Journal*, August 30, p. 531) requires comment. One of the main characteristics of myxomata of the atrium is their extreme friability. They have been likened to aspic, and even at open operation they have had to be removed piecemeal, as they have broken up at the slightest touch. There also seems to be a less common group which is firmer and which it may be possible to remove in one piece. Mr. Fatti had the good fortune to encounter one of these.

Any method which entails manipulation of these tumours should not be used if widespread emboli are to be avoided. The "considerable reorganization" required for hypothermia and open removal is more than justifiable, as it must be the method carrying the least risk, and it can and should be undertaken at once if a myxoma is encountered.—I am, etc.,

London, E.2.

J. R. BELCHER.

Anorexia Nervosa

SIR,—I am surprised that Dr. D. Stafford-Clark and others (*Journal*, August 16, p. 446) have bitten the unwitting cherry offered to them by Dr. Eirian Williams in his article on anorexia nervosa (*Journal*, July 26, p. 190). It would appear that he has not only succeeded in giving his patients something which they cannot swallow without assistance but also given certain reputable members of the profession dysphagia.

On reading the article I note that "psychiatrists, on the other hand, have claimed the illness in all its aspects as their own." In my very limited experience psychiatrists never

claim illnesses, only patients, and this artificial division between psychiatry and clinical medicine will continue whilst physicians, psychiatrists, and people like Dr. Williams try to divorce the mind from the stomach tube.—I am, etc.,

Bristol, 1.

A. D. M. SMITH.

SIR,—In his anxiety to score debating points off his colleagues Dr. Eirian Williams appears to me to overstep the limit set by ordinary courtesy when, in his letter (*Journal*, August 30, p. 563) he stigmatizes the nursing staff in psychiatric observation wards as "a pack of purposeful warders." Whether or not Dr. Williams has ever worked in an observation ward I do not know. From his remarks, which appear to be informed by ignorance as well as prejudice, I should judge that he has not. Had he done so he would be well aware that cases of anorexia nervosa are not among those cases of acute psychosis and other mental illness which are admitted by the Duly Authorized Officer or by the police to observation wards.

The number of cases in my experience requiring tube-feeding is very small, being limited to those suffering from severe depression or other forms of stupor. When tube feeding is used, there is no question of it being performed under barbiturate narcosis, as Dr. Williams implies. I doubt if the procedure differs in any way from that adopted in Dr. Williams's own wards, except that we prefer, for the sake of the patient, to carry out this distasteful procedure in the privacy of a side-ward rather than in the presence of 27 other patients. That tube-feeding is a rare necessity is due largely to the efforts of the nursing staff, who with great patience and skill manage to persuade the majority of the severely disturbed patients under their care to take adequate nourishment. They have no more enthusiasm for forcible tube-feeding than has the patient.

That patients in psychiatric observation wards are detained against their wishes is a fact. Nevertheless, it is, so far as the nursing staff are concerned, quite the least important aspect of their duties, which are therapeutic rather than custodial. During their period of duty they are constantly with severely disturbed patients whose behaviour is often characterized by gross degradation of habits and physical assaults upon the staff. For the most part these problems are dealt with with great patience, tact, and good humour, facts which are recognized not only by relatives but also, in many instances, by the patients themselves. If the uninformed layman can be generous in his appreciation of the work of the observation ward nursing staff, one would hope and expect that they could be spared the ill-informed strictures of Dr. Williams.—I am, etc.,

London, S.E.22.

F. A. WHITLOCK.

SIR,—I am reluctant to prolong this correspondence. Having written his article (*Journal*, July 26, p. 190) and essayed a spirited riposte to the reasoned but unanimous criticism it received, Dr. Eirian Williams had only to confine his reply (*Journal*, August 30, p. 563) to answering the criticism—if he could—or clarifying and consolidating his own position, however provocative, to have been gladly accorded the last word on this occasion. But instead he has chosen once again to make sweeping and unfounded assertions which are not only unsupported but are in fact insupportable. Observation wards are not staffed by "packs of purposeful warders" (whatever this is supposed to mean): like the wards of his own hospital, and of mine, they are staffed by nurses. Disagreement with his views does not necessarily imply remarkable ignorance, timidity, or covetousness; it could conceivably be the outcome of wider experience. Indeed, such experience may suggest that a doctor is not always wise to regard his patients as predestined losers in a contest in which he holds the trumps; so that he can blithely dismiss their helpless distress as mere chagrin that "the game, after all, was up." Medicine has never been as simple—or as insensitive—as that.—I am, etc.,

London, S.E.1.

D. STAFFORD-CLARK.

Imbecile Children

SIR,—Dr. John Burkinshaw (*Journal*, June 28, p. 1543) has stressed the value to parents of the recent provision by institutions of facilities for temporary admission. He also advocates use of mental deficiency hospitals for out-patient sessions and as a place for permanent admission only if the need eventually arises.

Dr. J. M. Crawford (*Journal*, July 26, p. 245) suggests that many ineducable children do better in hospital, if there is no occupation centre near their home. He says that he

would rather catch them young if they have to come to hospital, though he modifies this by saying that they should either go daily from home or live in hostels.

The danger of admitting young children to the large institution with big overcrowded wards is shown by the attached graph of deaths at the Fountain Hospital, 1955-8 (total 100), which demonstrates the high mortality in the immediate post-admission period. Only those deaths within two years of admission are charted, showing relationship to time of admission. The average age on admission was 2½ years, so that there is no adequate control group of older children available in this series, but our experience suggests that death and serious illness are more likely to occur among the younger and less mobile children. These considerations provide an additional reason for postponing the permanent admission of mentally defective children to institutions and for increasing the advice and assistance available to parents for their care at home, including the provision of additional occupation centres.—We are, etc.,

London, S.W.17.

EVELYN B. LIND,
BRIAN H. KIRMAN.

Arresting an Outbreak of Poliomyelitis

SIR,—Many of your readers will doubt whether I (*Journal*, August 2, p. 325) or Dr. M. Agerholm (*Journal*, September 6, p. 638) are qualified to comment on the virological and epidemiological problems of poliomyelitis. Our knowledge of these aspects is second-hand, and as mere dabblers in these fields we are inclined to pluck the flowers we like the look of. However, there are so many facets of a disease like poliomyelitis that the free-lance who can say what he likes may contribute to current problems, for the reason that he can express opinions which more important people that he can be debarré from communicating. This is specially noticeable when politics comes into the picture, but unfortunately, when this happens, an increasing number of experts are silenced, and public opinion is apt to be influenced less by the expert than by the amateur. This is a dangerous situation which I for one have no wish to aggravate.

As a student of poliomyelitis in its various aspects I have doubts about the ultimate efficacy of the present vaccination programme, and yet at the same time fully support what is

being done, for it seems to be the best available. I anticipate, however, that the shortcomings of the present vaccine will become even more apparent in the next year or two. I have often expressed dismay at the inadequacy of the research effort being devoted to the development of an oral vaccine, for I do not share the timidity which many feel in connexion with this method. Most experts agree that alimentary canal infection with polio viruses is an essential contribution to the maintenance of immunity in the community, so why not introduce this infection on one's own terms? Hence my delight that Dr. H. Koprowski and his colleagues (*Journal*, July 26, p. 187) have had the courage to make what still seems to me to be a very important contribution, and which I hope will boost the amount of research being done on the development of oral vaccines. Perhaps I may add that an Expert Committee of W.H.O. also advocates more work in this field.—I am, etc.,

Oxford.

W. RITCHIE RUSSELL.

Contraception by Inhibition of Ovulation

SIR,—Dr. B. H. Kirman's conscience seems troubled about the "permissibility" of the trial in Puerto Rico of an oral contraceptive (*Journal*, August 30, p. 565). On re-reading your annotation to which he refers (*Journal*, August 2, p. 297) I fail to understand this; it reports that many substances had been studied, and a field trial of one of them, "enavid," was only made after it had proved harmless in extensive animal tests and trials in women. Dr. Kirman implies that, because others have reported that substances not used in this trial have proved harmful, therefore the favourable reports of the value of enavid are somehow suspect. He may have special knowledge to support his doubts, but his letter does not show this.

The last sentence of Dr. Kirman's letter reads strangely. He says that a contraceptive pill is not a substitute for radical and costly measures to improve living standards in underdeveloped countries. I do not know that it had been suggested otherwise: but there is wide agreement on the urgent need to control the rapid increase in the population of these countries if social conditions are to improve.—I am, etc.,

St. Paul's Cray.

L. M. FRANKLIN.

Congenital Dislocation of the Hip

SIR,—I read your annotation (*Journal*, July 5, p. 38) with special interest, and venture to set out here some family data concerning congenital dislocation of the hip in three generations which might perhaps serve as case-material for research into this abnormality.

My sister was born in 1896 with a right-sided dislocation. So was I in 1900. There were no more children. Both deliveries were normal in every respect. There was no other case in our family. My sister's second son was born in February, 1926, after half an hour of labour: normal delivery, normal weight. I was in hospital for surgical treatment of my hip when my sister became pregnant. She visited me there, and my surgeon then impressed on me strongly that her infant should be x-rayed within six weeks of its birth, as only very early treatment gave any hope of complete success. Yet the parents refused to do so when the child was born. Nor did my sister's accoucheur, family doctor, and paediatrician advise the parents accordingly. I was absent from home at the time of delivery and saw my nephew for the first time when he started to walk. His waddling gait filled me with grave forebodings. I renewed my efforts and finally succeeded in having the child examined. It was ascertained that he had a left-sided dislocated hip. He was manipulated some months later by Professor Bruno Valentin, of Hanover. I do not know my nephew's radiological status, but he walks with a marked limp, tires easily, and is often in pain. He is now 32, a broad-chested six-footer. He managed to become a fine gymnast as a boy.

This nephew had his first child, a daughter, last February. At the father's request she was x-rayed at 8 or 9 weeks and

for he was convinced of India's need for gifted medical teachers. The Postgraduate Medical Institute which is coming into being at Delhi owes much to his proposals. In 1946 Hance came home to the India Office as Medical Adviser to the Secretary of State for India and as President of the India Office Board. At first he was closely concerned with finding suitable posts for officers of the I.M.S. retired from India on Independence Day, and his successful efforts on their behalf were greatly appreciated.

When the Commonwealth Relations Office was established Hance was appointed medical adviser to the Secretary of State, and he had to turn his attention to the medical aspects of the new high commission posts all over the Commonwealth. He was also concerned with the Colombo plan for technical aid and co-operation in South and South-east Asia. A pneumonectomy performed eleven years ago for proved bronchial carcinoma hardly interfered with his activities. He was at work again in a few months, travelling over the world on many occasions. On these journeys he found an oxygen mask helpful. Much of his time was given to interviewing overseas students with a view to advising them on suitable training. Three years ago the Government of Ceylon asked for his services under the Colombo plan to advise on the reorganization of the health services there. Promoted K.C.I.E. in 1946, he was created K.C.M.G. in the Coronation honours list in 1953. He was also a Knight of the Order of St. John of Jerusalem.

Increasing dyspnoea on exertion made him abandon his only recreation, fly-fishing, last year. To the very end he continued regularly to attend meetings of the Board of Governors of the Brompton Hospital and of the Institute of Ophthalmology, the Postgraduate Federation, and other bodies on which he served, facing his inevitable fate with resolution and deceiving his most intimate colleagues by his bold front. Sir Bennett Hance was twice married, first in 1916 to Catherine, only daughter of Dr. C. L. Leonard, of Philadelphia, by whom he had two daughters, and secondly in 1938 to Frau Richildis von Kaan, of Vienna, who survives him.

W. M. FRAZER, O.B.E., M.D., M.Sc., D.P.H.

Professor William Frazer, formerly medical officer of health for the City and Port of Liverpool and professor of public health at the University of Liverpool, died on September 8 in the Royal Southern Hospital, Liverpool, after a short illness. He was 70 years of age.

William Mowl Frazer was born in Liverpool on March 7, 1888, and was educated at the Oakes Institute, Liverpool, and later at the Universities of Liverpool and London. He graduated M.Sc. at the former university in 1909, and shortly afterwards obtained a post in the education officer's department of the London County Council. It was not until he returned from service in the King's (Liverpool) Regiment during the first world war that he became a medical student. Having graduated M.B., Ch.B. at Liverpool in 1921 at the age of 33, he took the D.P.H. in the following year and proceeded to the degree of M.D. in 1928. He was called to the Bar by Gray's Inn in 1923. After holding several resident appointments in hospitals in Liverpool he

[Liverpool Daily Post and Echo]

became assistant medical officer at the Manchester Sanatorium at Baguley before being appointed assistant medical officer of health at Blackburn. In 1925 he was appointed medical officer of health for the county borough of Dewsbury, and four years later he moved to Hull, where besides

being M.O.H. of the city he was medical officer to the Goole Port Sanitary Authority.

In 1931 he was appointed medical officer of health for the City and Port of Liverpool and medical officer to the Liverpool Education Authority, holding these posts until his retirement in 1953. When he went to Liverpool he was appointed senior lecturer in public health at the university, and in 1933 he became professor of hygiene (later of public health). On his retirement he was appointed emeritus professor.

Frazer soon became one of the leading public health workers in the British Isles. A gifted writer, he contributed many articles to medical and other journals, and he was also author of several books, including a textbook of public health. He served on numerous committees, including committees of the Ministry of Health and of the Medical Research Council. A medical officer of the health committee of the Association of Municipal Corporations, he was also honorary treasurer of the Association of Sea and Air Port Health Authorities of the British Isles. In 1948 he became a member of the Liverpool Regional Hospital Board and of the Board of Governors of the United Liverpool Hospitals, and until his death he acted as chairman of the establishment committees of both bodies. Vice-president of the Section of Public Health at the Annual Meeting of the B.M.A. in 1933, he was president of the Section of Preventive Medicine at the Liverpool Meeting in 1950. Four years later he was News-holme lecturer at the University of London, choosing for his subject "State Medicine in the Nineteenth Century." Professor Frazer was an honorary fellow of the American Public Health Association.

He married in 1917 Gladys Mary Gubbins, who survives him with a son and a daughter, both of whom are graduates in medicine of Liverpool University.

A.B.S. writes: During his official life in Liverpool Professor Frazer was concerned mainly with the development of the hospital service and with slum clearance. In 1931 the Local Government Act of 1929 had placed under the health department some 21 hospitals and institutions containing about 10,000 beds which were underdeveloped and understaffed. It was his duty to survey these hospitals and plan improvements. He instituted laboratory facilities and x-ray departments, and built up specialist teams in the various municipal hospitals. As a result, when war broke out in 1939 the hospital service of Liverpool was well prepared to undertake the strain that was put upon it during the early years of the second world war. In particular he emphasized the importance of co-operation with the voluntary hospitals and the university, and encouraged the use of the municipal hospitals in the training of medical and other students. It was he who suggested to the vice-chancellor of the university the formation of the body which became known as the Liverpool Hospitals Joint Advisory Committee. He also was active in the founding of the chair of child health in Liverpool. During the second world war he was responsible for the casualty services in Liverpool, and for services to civil defence he was awarded the O.B.E. in 1939.

In the field of housing, great strides were made between 1935 and 1939. During that period he represented more than 12,000 slum houses for demolition. This campaign, the largest in the history of Liverpool, would have probably solved Liverpool's slum problem had it not been interrupted by the outbreak of war.

Professor Frazer was a man of high principles and a strict ethical code. He will long be remembered not merely for outstanding academic merit, brilliance of intellect, and a phenomenal memory, but also for profound wisdom which inspired his resolute approach to the practical problems of public health administration. He was not an easy man to get to know, but with knowledge of the man came a real affection for his abilities and intellect.

We are indebted to Sir ALLEN DALEY for the following appreciation: The death at the age of 70 after three days'

illness of Professor W. M. Frazer will leave a sad gap in the ranks of those prominent in public health a generation ago. He did not make friends quickly or easily, but all who knew him well were devoted to him. My first contact with him was when I was M.O.H. of Blackburn. I was on the look-out for talent and heard from one of my assistants that Dr. Melville Mackenzie had been greatly impressed by a very bright young man named Frazer whom he had met at a Liverpool Fever Hospital and who was then at the Baguley Sanatorium, Manchester. I arranged to see him and received so favourable an impression that I got him appointed as assistant medical officer of health of Blackburn when the next vacancy occurred. After passing in rapid succession through other appointments in the public health service he became M.O.H. of the City and Port of Liverpool. He filling that post with great distinction for 22 years. He was appointed O.B.E. in 1939—an honour which many hoped would have been added to in his later years.

He was always interested in hospitals, and, along with his deputy, Dr. C. O. Stallybrass, did much to improve the Liverpool municipal hospitals. Though, like many of his generation, he deplored the nationalization of the hospitals, he maintained his zest for hospital administration after the start of the National Health Service in 1948, and after his retirement the work of the Liverpool Regional Hospital Board occupied the greater part of his time. He was among the few medical officers of health appointed in 1948 to a regional hospital board. For some years before his retirement he was the trusted adviser of the health committee of the Association of Municipal Corporations and was a member of the Committee on the Health of Seamen of the International Labour Office. He always had a deep interest. He was the successor of the first M.O.H. of this country, as befits the history of public health, and in 1947 he wrote an excellent biography of Dr. W. H. Duncan, who was M.O.H. of Liverpool from 1847 until 1863. His appetite thus whetted, he embarked on his monumental work, *A History of English Public Health: 1834-1939*. For many months he spent every Saturday afternoon in the library of the Liverpool Athenaeum reading old records. A very long time ago Livingstones of Edinburgh first published Husband's *Handbook of Forensic Medicine and Medical Police* (later named *Forensic Medicine, Toxicology and Public Health*): and some forty years ago it was split into separate volumes, and Dr. E. W. Hope, then M.O.H. of Liverpool, was responsible for the one on public health. After Frazer became M.O.H. of Liverpool the revision of further editions was entrusted to him. He almost rewrote several of them, including the thirteenth.

H. B. RODERICK, O.B.E., M.D., M.Chir., F.R.C.S.
Mr. H. B. Roderick, formerly honorary surgeon on the staff of Addenbrooke's Hospital, Cambridge, died at the age of 84 in the hospital to which he had given so many years of service.

Henry Buckley Roderick was born at Llanelly on August 19, 1874, the son of a banker and nephew of a general practitioner in that town. From Bath College he went on to Emmanuel College, Cambridge, at the age of 17, and graduated B.A., with honours, in 1894. Going to St. George's Hospital for his clinical training, he took the degrees of M.B., B.Ch. in 1898, proceeding to the M.D. in 1902 and the M.Chir. in 1916. He took the D.P.H. in 1903. At St. George's he held house appointments and then became surgical registrar. In 1900 he returned to Cambridge, starting in general practice and taking over the post of police surgeon. Within a year, however, he was appointed to a demonstratorship of surgery in the university medical school to assist Mr. Joseph Griffiths, who was acting as deputy professor of surgery after the death of Sir George Humphrey. He continued in this appointment when Howard Marsh became professor of surgery in 1903.

and, although the professorship of surgery was suspended after the death of Marsh in 1915, Roderick continued to hold the demonstratorship after his return from military service, lecturing in operative surgery and surgical pathology until 1926. From 1928 to 1939 he served the medical school further as supervisor and examiner in surgery.

Roderick's early interest in military medicine was shown by his service as medical officer to the University Rifle Volunteers from 1901 to 1908, and from 1908 to 1914 as C.O. of the medical contingent of the University O.T.C. In 1914 he joined the 1st Eastern General Hospital, R.A.M.C., T.A., with the rank of major. He was with this unit in Cambridge until 1917, when he went to France as lieutenant-colonel commanding the 55th General Hospital until the end of the war. He was twice mentioned in dispatches and his services were rewarded with the O.B.E. (Mil.) and the T.D. On his return to Cambridge in 1919 he was appointed honorary surgeon to Addenbrooke's Hospital. In 1932 he was elected F.R.C.S.

Roderick had always been interested in the surgery of bones and joints, and, although essentially a general surgeon by training, he set out to promote in every way the interests of orthopaedic and traumatic surgery in the Cambridge area. He started special orthopaedic out-patient sessions at Addenbrooke's Hospital, where he also used many of his beds for orthopaedic patients, and with the help of voluntary workers in the Cambridge branch of the B.R.C.S. he organized orthopaedic clinics in the rural areas and at the hospitals at Wisbech and Huntingdon, where he held honorary appointments. His constant enthusiasm acted as a great stimulus to public interest in the prevention and treatment of crippling disease, not only in Cambridgeshire but in the neighbouring counties also, and left lasting results in the foundations from which the present area orthopaedic services have developed. Although his constant campaign for provision of a long-stay orthopaedic hospital for East Anglia was defeated, when it at last seemed about to succeed, by the outbreak of war in 1939, he lived to see adequate provision for such patients through the increase of hospital beds under the E.M.S. and their reorganization in the National Health Service, and his work was not in vain, for it had shown where the need lay. In 1939 he had reached retiring age from the hospital staff, but carried on as a voluntary deputy surgeon until the return of others who had gone on military service made his presence unnecessary, when he quietly dropped out.

A leading figure in medical affairs in East Anglia, Roderick was president of the Cambridge and Huntingdon Branch of the B.M.A. in 1933, when he also acted as chief host for the British Orthopaedic Association at its annual meeting held that year in Cambridge. Three years later he was a vice-president of the Section of the History of Medicine at the Annual Meeting of the B.M.A. Outside his professional work he was a man of wide knowledge, with many interests and activities. For many years he was a churchwarden of Great St. Mary's, the University Church. An ardent Freemason, he was a Past Grand Deacon of England and a Past Deputy Provincial Grand Master. A founder member and past president of the Cambridge Rotary Club, he was a strong supporter of the British Legion and a past president of the Cambridge branch.

Among his innumerable friends there must be many Cambridge medical graduates and past examiners in surgery who remember with affection his constant helpfulness and his whimsical humour. It is good to know that he had so many years of active and happy retirement before failing health in the last three years limited his capacity for enjoyment. Much of the last months of his life was spent in hospital, but he kept his courage and his thoughtfulness for others to the end. His long life was one of good service which brought him much happiness.

In 1908 Mr. Roderick married Hilda, daughter of John Clay, of Cambridge. She survives him. They had four sons and three daughters.

E. W. B.

**CHRISTINE M. STACEY, M.B., B.S.
M.R.C.O.G., M.M.S.A.**

Dr. Christine M. Stacey, whose death occurred last month, was gynaecological surgeon at St. Olave's Hospital and consultant venereologist at King's College Hospital.

Christine Margaret Stacey was born on September 24, 1910, and studied medicine at the London School of Medicine for Women and the Royal Free Hospital. After qualifying in 1936 and graduating M.B., B.S. in the following year, she held resident posts at the Royal Free Hospital, the Royal Northern Hospital, and the Mothers' Hospital, Clapton. Some years later she joined the staff of this last hospital as obstetric surgeon. Having passed the examination for the D.R.C.O.G. in 1941, she took the M.R.C.O.G. and M.M.S.A. in 1948, and was elected to the staff of St. Olave's Hospital as gynaecological surgeon. She was especially interested in problems of fertility and had had long experience in the diagnosis and treatment of venereal diseases. She joined the staff of King's College Hospital as a consultant venereologist in 1952. Dr. Stacey married in 1940 Mr. A. J. Heriot, who is a surgeon on the staff of King's College Hospital. They had two sons.

Dr. FRANCIS L. LYDON writes: It was with great regret that I learned of the recent death of Dr. C. M. Stacey, whom I first met some six years ago on her appointment as consultant to the special department at King's College Hospital. Her wide knowledge of the venereal diseases was only to be expected, as she previously held the post of registrar to the female venereal clinic at Guy's Hospital, but, since she held higher degrees in gynaecology and surgery, with much practical experience in these branches, her appointment was especially gratifying. During our few years together I was constantly grateful to her for her advice and help in the many difficult cases attending the department, and her early realization that diseases such as lymphogranuloma venereum and granuloma venereum were likely to increase owing to the movement of peoples led to their rapid diagnosis and treatment—which is so important in preventing their spread. Opportunities for research are few in a busy department, but Dr. Stacey was ever ready to co-operate in trying to elucidate the many gaps in our knowledge of our particular specialty. I shall always remember her as a kind and gracious lady who in her last few years tried to continue her work with great and uncompromising courage in the face of illness. I am sure that all my colleagues at King's and her many friends would wish to join me in extending to her husband and her family our deep sympathy and our great affection.

DUNCAN DAVIDSON, M.C., D.M., D.P.H.

Dr. Duncan Davidson, who died at his home in Kenilworth on September 2 at the age of 78, will be sadly missed by his many friends and patients in the city of Coventry and in Warwickshire.

Born in Coventry, the son of Dr. Charles Davidson, who had formerly been a surgeon in the Royal Navy, Duncan Davidson was educated at Malvern College and at Brasenose College, Oxford, which he left in 1901 to fight in the South African war. Returning to Oxford in 1902, he completed his preclinical course and went on to the London Hospital, graduating B.M., B.Ch. in 1906. After holding the appointments of house-physician, receiving-room officer, and ophthalmic house-surgeon at the London, he became a clinical assistant in the medical out-patients department of the Hospital for Sick Children at Great Ormond Street. In 1910 he joined his father in practice in Coventry, taking the D.P.H. in the following year. During the first world war he was a captain in the R.A.M.C.(T.) attached to the Howitzer Brigade, serving in France and Italy, and was awarded the Military Cross. After the war he proceeded to the degree of D.M. at Oxford, and was appointed assistant ophthalmic surgeon to the Coventry and Warwickshire Hospital, an appointment he held until his retirement in 1950.

He was chairman of the Coventry Division of the British Medical Association in 1926 and 1927. Among his many other activities he was a justice of the peace, a Freemason, and a member of various City Guilds, and he served on the boards of governors of many schools and charities. A sincere Christian, he was formerly treasurer and vicar's warden of Holy Trinity Church, Coventry.

Duncan Davidson, in spite of increasing pain and ill-health, was a man who never spared himself in working for the well-being of his fellow men. His wide interests and his unfailing kindness and modesty tended to mask the tremendous courage which was the true essence of his great spirit. One cannot write of him without thinking of his wife, whose love and devotion has radiated throughout their lives together. Our great sympathy goes out to her and her family.—G. C. V.

S. KATE K. HASLAM, L.S.A., M.D.

Dr. Kate Haslam, who was formerly in practice in North London and assistant school medical officer under the London County Council, died on August 24 at the age of 85.

Sarah Kate Keeling Haslam was born in 1873. She studied medicine at the London School of Medicine for Women, qualifying L.S.A. in 1901 and in the same year taking the degree of M.D. of Brussels. After qualification she held a number of junior hospital posts, including those of clinical assistant in the maternity department at the New Hospital for Women and clinical assistant in the skin department at the Royal Free Hospital. She was also for a time a medical officer at the Retreat, at York. After holding these appointments she went into general practice in North London, where she remained for a number of years. Much admired for her wisdom and kindness, she thoroughly approved of the suffragette movement, though she could not actively participate in it. After the first world war Dr. Haslam worked as an assistant school medical officer in London, a post which she held until she retired from practice, though not from active work. She was much loved by patients and medical colleagues alike, and was one of a fine generation of women doctors who had much to contribute in what was then a new field of work.

SIR DARCY COWAN, M.B., F.R.A.C.P.

The obituary of Sir Darcy Cowan was printed in the *Journal* of June 21 (p. 1484). Sir HENRY NEWLAND and Dr. ROGER ANGOVE, the authors of the following appreciation, wish to acknowledge with thanks the information supplied by many friends of the late Sir Darcy Cowan.

No obituary of the late Sir Darcy Cowan would be complete without some reference to the personality and career of his father, whose capacity and sterling character were notable in his son. James Cowan was born in Ulster in 1848 and four years later came with his parents to South Australia. He entered his father's coaching and farming business, but before he was out of his teens he started business on his own account as a mail contractor and small farmer. His enterprise led him to purchase a flour-mill, which proved to be a very profitable investment. Within a few years James Cowan was the proprietor of mills in four country towns and also of wharves at Port Pirie and Port Gawler. The mills were merged into the Adelaide Milling Co. By his investments in pastoral properties he accumulated considerable capital. He assisted in the formation of a coke company at Port Pirie, the genesis of the huge smelting works of to-day. In 1890 Mr. James Cowan was elected Member of Parliament for Yatala, and at once made a great impression on the House in debates, and was regarded as a possible Minister of the Crown. He had been a Member of Parliament for only a few months in 1890 when he had a fatal accident.

The fine career of James Cowan reveals a strength of purpose that resided in his son Darcy in great measure.

Neither was daunted by opposition or failure, but pressed on to his objective and ultimate success. Darcy Cowan's crusade against tuberculosis began after he had attended the famous clinic of Dr. Philip at Edinburgh, and he never wavered in his quest. The genesis of the National Association for the Prevention of Tuberculosis in Australia dates back to the formation of the South Australian Tuberculosis Association in 1943. Dr. (later Sir) Darcy Cowan planned the State body on the model of others he had studied in overseas centres.

A little later a similar association was formed in Western Australia and approaches were made to the B.M.A. to give official support to a national organization. At the Medical Congress held in Perth in 1950 a resolution was carried approving the proposals submitted. A provisional committee was formed to draft a constitution. Medical men from each capital city returned to their homes determined to assist in this sponsorship. Sir Henry Newland was appointed as president and Dr. Darcy Cowan as honorary secretary, *pro tem*. At the first meeting of the National Council in Adelaide the constitution was formally adopted and Sir Henry Newland named as Foundation President. Dr. Cowan continued in the guiding role of honorary secretary. Affiliation was immediately granted by the National Association for the Prevention of Tuberculosis in London and the International Union, and a Council of Honour formed on which the Governor-General and the Governors of each of the six States accepted seats. The new body found great assistance from the ready co-operation given by older-established national associations in other lands. Films, printed matter, and radio platters were made available by N.T.A., New York, which enabled N.A.P.T.A. to extend propaganda work within the Commonwealth. From his own membership and knowledge of the work of the American Trudeau Society, Dr. Cowan sought next to establish a similar medical section in Australia. Thus was the Australian Laennec Society organized. To-day the society has a branch in most states of the Commonwealth, and undertakes studies at scientific levels. Darcy Cowan served as president of the Laennec Society in 1955. In 1957 his fellow workers determined to show him honour by offering a prize for graduates, to be known as "the Sir Darcy Cowan Prize." This will be awarded for the first time this year.

It seems fitting to record at random some of the miscellaneous achievements and positions which Sir Darcy held. He was one of the very few triple blues of the Adelaide University. His love of tennis persisted throughout his life. He became a member of the Grounds Committee of the South Australian Lawn Tennis Association in 1920, and was chairman for many years. He was then vice-president for 20 years, and an honorary organizer for the 1952 Davis Cup challenge round. As a player, he will be remembered as a skilful exponent of the game who always enjoyed a match and played it in true sporting spirit. It was his policy and direction as chairman of the Grounds Committee which brought the Memorial Drive courts to a state described by overseas authorities as "as good as any courts in the world, not excluding Wimbledon."

He served his own teaching hospital, the Royal Adelaide, for many years as honorary physician and later as honorary consulting physician, and was also the first person to be appointed senior physician to the chest clinic and Frome ward. During this time he was the lecturer in pulmonary tuberculosis at the University of Adelaide. He was president of the South Australian Branch of the British Medical Association in 1935 and 1936.

My (H.S.N.) more intimate association with Darcy Cowan began when he invited me to be president of the South Australian Tuberculosis Association. This post I accepted on two conditions: one, that a more militant attitude should be adopted in the prevention of tuberculosis, and that an Australian National Association for the Prevention of Tuberculosis should be formed to co-ordinate the activities of the states of the Commonwealth and to be the medium of approach to the Commonwealth Government. Sir Darcy agreed to these conditions and most loyally sought

to fulfil them. It was a notable triumph for him when the National Association for the Prevention of Tuberculosis in Australia met in Sydney and was attended by delegates not only from Australia and New Zealand but from several Asian countries.

Until the time when failing health forced him to retire from all offices, Sir Darcy Cowan fought the good fight with vigour. His remarkable knowledge and enthusiasm made him a most acceptable leader of the various councils in both national and State spheres. He expected action and constant progress, and fearlessly criticized any appearance of *laissez-faire* or complacency in either official or voluntary quarters. With his old friend and associate, Sir Harry Wunderly, he planned for the time when tuberculosis might be eradicated in Australia. He constantly "prodded" Ministers of the Crown, members of the profession, his colleagues, and subordinates to improve the lot of sufferers and to assist in the final victory over this disease.

Sir Darcy Cowan was for years the official Australian correspondent for N.A.P.T. London, and he was a member of the American College of Chest Physicians and of the Trudeau Society. He was known and respected by leaders in the campaign in many lands. At the first International Conference on Tuberculosis in Sydney in 1955 Sir Darcy played a great part in the organization, and he personally went to live in the residential college so that he could develop his knowledge of fellow-workers from all Asian countries. Sir Darcy was a great Australian, and truly a great world citizen.

Vital Statistics

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the years 1949-57 are shown thus ----, the figures for 1958 thus ———. Except for the curves showing notifications in 1958, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Week Ending September 6

Infectious diseases were less prevalent in England and Wales during the week ending September 6. The largest falls in the number of notifications were 833 for measles, from 2,810 to 1,977, 122 for food-poisoning, from 397 to 275, and 60 for dysentery, from 376 to 316.

The largest declines in the incidence of measles were 96 in Lancashire, from 411 to 315, 81 in London, from 199 to 118, 49 in Middlesex, from 156 to 107, and 49 in Warwickshire, from 124 to 75. The number of notifications of scarlet fever, 304, was 18 more than in the preceding week; there were no large fluctuations in the local returns. 791 cases of whooping-cough were notified, and these were 19 fewer than in the preceding week; the largest fluctuation in the local trends was a rise of 61 in Lancashire, from 58 to 119. 3 cases of diphtheria were notified compared with 0 in the preceding week; 2 of the cases were notified in Plymouth C.B.

The notifications of acute poliomyelitis numbered 80, and these were 14 more for paralytic and 12 fewer for non-paralytic cases than in the preceding week. The largest returns were Yorkshire West Riding 17 (Leeds C.B. 8, Castleford M.B. 2), Lancashire 14 (Burnley C.B. 5, Manchester C.B. 2, Kirkby U.D. 2), Devonshire 13 (Plymouth C.B. 11), Essex 4, and Kent 4.

The largest centres of dysentery were Yorkshire West Riding 63 (Thorne R.D. 17, Leeds C.B. 10), Lancashire 52 (Liverpool C.B. 16, Blackpool C.B. 10), London 36, Devonshire 27 (Paignton U.D. 23), and Warwickshire 21 (Coventry C.B. 12).

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending August 30 (No. 35) and corresponding week 1957.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the whole of England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES	1958					1957

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenza pneumonia.
‡ Includes puerperal pyrexia.

Medical News

Postgraduate Travelling Fellowships.—Details of postgraduate travelling fellowships offered by the British Postgraduate Medical Federation to registered medical and dental practitioners holding appointments at the teaching hospitals, medical or dental schools, and postgraduate institutes of the University of London are given in the advertisement columns (page 53). These are tenable at other centres in the United Kingdom or abroad.

Buswell Fellowships.—The University of Rochester School of Medicine and Dentistry announces a series of Buswell Fellowships for graduates of approved medical schools who wish to carry out research there. The object of the fellowships is to assist well-qualified doctors to prepare for academic careers. Junior fellowships carry a basic stipend of \$4,500 \$6,000 a year, senior fellowships \$5,500-\$8,000. Applications will be received at any time. Further details and application forms are obtainable from Dr. L. E. YOUNG, University of Rochester Medical Center, 260, Crittenden Boulevard, Rochester, 20, New York.

Films for G.P.s.—A film on the physio-pathology of hypertension, made for Pfizer Ltd. by Dr. N. P. SCHENKER, was shown to an invited audience in London last week. This film is one of a series intended primarily for the general practitioner and designed to offer a concise 30-minute refresher course on the latest developments in important fields of medicine. "The Physio-pathology of Hypertension" surveys the present state of knowledge of the reflex regulation of arterial pressure. The principal technical adviser during the making of the film was Professor C. HEYMANS, of Ghent, whose work on the carotid sinus won him the Nobel Prize in 1938. Before the film was shown Professor Heymans gave a short talk on the place of the baroreceptors of the carotid sinus and aortic arch in the control of arterial pressure, and the film itself demonstrated the animal experiments on which modern views on this subject are based. Professor J. McMICAL, F.R.S., took the chair at an informal discussion after the film.

International Children's Centre.—Applications are invited for the 1959-60 Nestlé Fellowship (one million francs) from physicians wishing to specialize in nutrition. Candidates, who must have a command of French, may obtain further information about the fellowship from the International Children's Centre, Château de Longchamp, Bois de Boulogne, Paris, 16. Among other activities the centre holds international training courses on medical, psychological, and social aspects of maternal and child welfare. These courses are for the discussion of recent technical advances and their practical application. Details of these courses may also be obtained from the centre.

Paediatric Dietary.—A third edition of *Diets for Sick Children* has been published from the Hospital for Sick Children, Gt. Ormond Street, London, W.C.1 (pp. 16; 1s. net). It includes diets and recipes for use in such metabolic disorders as coeliac disease, galactosaemia, and phenylketonuria, for diabetes, and for children with diseases of the liver or kidneys.

Dental Radiology.—A British Society of Dental Radiology has been established. This follows meetings at the Royal Dental Hospital, London, under the chairmanship of Dr. SYDNEY BLACKMAN, of representatives from the radiological departments of dental schools and hospitals in the United Kingdom. The society's objects include the promotion of dental radiology and research and the establishment of dental radiology as a specialty with a registrable diploma. A programme of scientific meetings is being arranged for next year. Those interested should apply to Mr. GUY POYTON, F.D.S., Eastman Dental Hospital, Gray's Inn Road, London, W.C.1.

All-India Institute of Public Health, Calcutta.—A small team of W.H.O. consultants is shortly visiting the All-India Institute of Public Health and Hygiene, Calcutta, to advise on the educational facilities there. Two of the team are from Britain, Colonel C. A. BOZMAN, director of the Wellcome Museum of Medical Science, London, and Professor T. MCKEOWN, professor of social medicine at Birmingham.

Osborne.—With the approval of the Queen, the Minister of Works has appointed Surgeon Rear-Admiral E. T. S. RUDD to be house governor and medical superintendent of King Edward VII Convalescent Home for Officers at Osborne, Isle of Wight. He succeeds Lieutenant-General Sir NEIL CANTLIE. Admiral Rudd will take up his appointment on November 1.

Professor M. E. DeBakey, of Houston, U.S.A., has been awarded the 1958 Alvarenga prize of the College of Physicians of Philadelphia.

COMING EVENTS

Royal College of Obstetricians and Gynaecologists.—Tickets for the Green-Armytage Anglo-American Sterility Lecture on September 26 (see *Journal*, September 13, p. 699) are obtainable from the secretary of the College, 58, Queen Anne Street, London, W.1.

Medical Protection Society.—Annual meeting, 3 p.m. on October 1, at the society's offices, Victory House, Leicester Square, London, W.C.2.

Association of Clinical Pathologists.—61st general meeting, October 2-4, at the Royal College of Surgeons. The meeting will include a symposium commemorating the centenary of the publication of Virchow's *Die Cellularpathologie*. Details from Dr. J. N. CUMINGS, The National Hospital for Nervous Diseases, Queen Square, London, W.C.1.

Institute of Diseases of the Chest.—Clinical demonstrations (without fee) for medical practitioners, on Fridays at 5 p.m. from October 3 to December 12. Details from the secretary of the Institute, Brompton, London, S.W.3.

Course in Hypnosis.—Week-end course on hypnosis in medicine and dentistry, Manchester, October 4 and 5. Details from hon. secretary, North-western Branch of Dental and Medical Society for the Study of Hypnosis, 105, Cavendish Road, Salford, 8.

Birmingham University, Faculty of Medicine.—Sir ERIC JAMES, High Master of Manchester Grammar School, will give the inaugural address on October 6, at 3 p.m., at Nuffield House, Queen Elizabeth Hospital.

Royal College of Surgeons of England.—Monthly subscription dinners (30s.) will be held on October 8, November 12, and December 10. Details from the deputy secretary of the College, Lincoln's Inn Fields, London, W.C.2.

Sheffield University, Faculty of Medicine.—Mr. WILLIAM DOOLIN, editor of the *Irish Journal of Medical Science*, will give the inaugural address in the Firth Hall on October 10, at 5 p.m.

British Postgraduate Medical Federation.—Sir EDWARD SALISBURY, F.R.S., will give the inaugural lecture of the 1958-9 series on the "Scientific Basis of Medicine," on October 16, at 5.30 p.m. at the Senate House, London University. His subject will be "The Influence of Botany on Health and Disease."

British Council for the Welfare of Spastics.—One-day conference in Bristol for members of the medical profession, November 8, under the chairmanship of Professor A. V. NEALE. Tickets from the council, 13, Suffolk Street, London, S.W.1.

St. John Ambulance Brigade.—Surgeons' week-end conference and dinner, November 1 and 2, at B.M.A. House. Details from the conference secretary, 8, Grosvenor Crescent, London, S.W.1.

OUR EXPERT replies: One of the greatest possible tragedies in a child's life is for there to be delay in the diagnosis of a congenital dislocation of the hip, since the prognosis is almost universally excellent in the first few months of life but with an increasingly high failure rate if treatment is instituted later than this. The main essential, therefore, is to attempt early diagnosis. Even in these days it is frequently not diagnosed before walking starts. Two of the most obvious signs are abnormal creases in the leg and limited abduction. Caffey's figure refers to infants on

the leg and limited abduction. Caney's figure refers to infants on

the whole younger than 5 months, and if these skin creases persist at 5 months they often indicate a congenitally dislocated hip. It is appreciated that abnormal creases may occur in the presence of a normal hip; on the other hand, it is rare to see an abnormal hip without abnormal skin creases. Equally abduction may be normal in a hip which goes on to subluxation, and in the same article by Caffey he mentions two such cases; conversely, he states that 44.2% of infants had restriction of abduction, although the hips were normal. We are faced with the situation of trying to find which cases give us enough doubt to advise x-ray examination. Abnormal skin creases and limited abduction are in themselves not infallible but are certainly most suspicious.

Chemotherapy for Pulmonary Tuberculosis.—Dr. ROIF OESTREICHER (Baltimore, Maryland, U.S.A.) writes: I cannot but voice my objections to the views presented in an answer to a question ("Any Questions?" July 19, p. 179). Since 1955 determinations of biologically effective isoniazid serum levels have been in clinical use. On the average, 30% of adults are "rapid inactivators" of isoniazid—i.e., they metabolize this drug to such an extent as to be biologically ineffective. The daily dose of isoniazid, therefore, must be determined by serum level determinations. To treat a case of pulmonary tuberculosis with 1 g. of streptomycin and 200 mg. of isoniazid daily is to invite the emergence of streptomycin-resistant organisms, because under these conditions isoniazid has a very small chance to reach therapeutic levels. Indeed, among several hundreds of patients whose isoniazid serum levels were determined and who were under my care, only one had a biologically effective isoniazid serum level (without concomitant administration of aromatic amines) with a "loading" dose of 2 mg./kg. body weight, a dose which corresponds to a daily dose of 200 mg. for the average adult. I do realize, however, that isoniazid level determinations by bioassay are not readily available in many institutions. Therefore a therapy for a person under 40 years of age, excreting presumably drug-sensitive organisms, should consist of streptomycin 1 g. and isoniazid 8–16 mg./kg. body weight daily, and P.A.S. 10–12 g. daily. Should the patient have gastro-intestinal difficulties due to P.A.S., P.A.B.A. in the same dosage may be given. To avoid the neurotoxic effects of isoniazid, pyridoxine hydrochloride 50–100 mg daily should be given in every case. I subscribe wholeheartedly to the view that streptomycin for long periods of time will cause serious cochlear or labyrinthine damage in the elderly.

I think that the question itself brings up once more the sad theme of the ever-increasing number of patients who excrete drug-resistant organisms, who cannot be operated on for various reasons, and who thus join the ranks of custodial cases for the remainder of their wretched lives. The question could have been answered with one sentence: admit the patient to a chest hospital, where he will be treated by competent chest physicians.

OUR EXPERT replies: Dr. Oestreicher raises an important theoretical point. It is, of course, well known that some 30% of adults are "rapid inactivators" of isoniazid. On theoretical grounds it is certainly reasonable to expect that such patients would require higher doses of isoniazid. But in practice this seems unlikely. In the British Medical Research Council series, and in many centres in this country, the standard dose of isoniazid has been 100 mg. twice daily. Yet when this dose is combined with streptomycin 1 g. daily the incidence of drug resistance is very low indeed,¹ and in some series nil.^{2,3} In the latter two series the rate of sputum conversion to negative was 100%. Although isoniazid serum levels were not carried out on these patients, it seems probable that there were an appreciable number of "rapid inactivators" among them. Yet the relatively small dose of isoniazid appears to have been entirely effective. Such a dose also avoids the risk of peripheral neuritis and the necessity of giving pyridoxine. It is far more dangerous to follow the practice, unfortunately so widespread, of giving intermittent streptomycin with daily isoniazid. The relatively high incidence of drug resistance on this regime was demonstrated in the British Medical Research Council controlled trials over five years ago. In tuberculosis, as in other diseases, it is important that treatment should be founded not on purely theoretical considerations but on properly designed practical trials. As a result, at least in some areas of this country, the number of patients who excrete drug-resistant organisms is steadily decreasing, not increasing as Dr. Oestreicher suggests.

Brucella Abortus in Milk.—Dr. J. M. ROSS (Senior Medical Officer, Ministry of Health, London, W.1) writes: May I draw your attention to a somewhat misleading answer to the question on the action necessary on finding *Br. abortus* in milk ("Any Questions?" July 26, p. 260)? Regulation 20 of the Milk and Dairies Regulations, 1949, empowers local authorities to impose control measures when there is danger of any disease being contracted by man through the consumption of milk: this covers the risk of milk-borne human brucellosis, whether due to *Br. abortus* or *Br. melitensis*. If a medical officer of health has evidence which satisfies him that any person is suffering from disease caused by the consumption of milk, or that milk is being sold which is infected with disease communicable to man, he can either stop the sale or allow such sale only on the condition that the milk is first so treated as to be made safe; in practice, this means pasteurization. If the medical officer of health has no more than reasonable grounds for suspecting a milk supply either of having caused disease in a consumer or of being pathogenic to man, he can only impose treatment of milk before sale: he cannot stop sale on suspicion. Milk whey and other agglutination tests are useful for detecting brucella infection in dairy herds. They demonstrate the presence of brucella agglutinins, but they are not evidence of the presence of the organism itself in the milk. The "ring" test provides a valuable and simple means of screening milk samples and selecting those which should be submitted to the longer techniques of special culture methods or guinea-pig inoculation; only such techniques can provide satisfactory evidence that a milk is infected, or, at least, was infected when the sample was taken. The selective medium which Mair¹ recommends for the isolation of *Br. abortus* in herd milk gives a result in 4–5 days. Guinea-pig inoculation takes some 6–7 weeks to give results, and the length of this interval creates certain administrative difficulties in dealing with milk-borne brucellosis, because the secretion of the organism in the milk is limited to certain periods, some 6–8 weeks, at calving time. The milk concerned may well have ceased to be infected by the time that the result of the biological test has become available some six weeks after the sample has been taken. To keep the picture in proper perspective, one should add that (1) over 92% of all milk sold in this country is now heat-treated, and (2) the evidence suggests that most current cases of undulant fever are not due to the ingestion of infected milk but to contact with infected material from occupational or other circumstances.

Gluten-free Diets.—Mr. J. K. FLEMING, chief chemist of A. & R. Scott Ltd., writes: In their article on gluten-free diets (August 2, p. 299) Dr. R. F. Fletcher and Miss Marjorie Y. McCrick give a list of the gluten-free products of various manufacturers. In case there is any possibility of confusion between those of our products which do not or do contain gluten, I should like to point out that A. & R. Scott Ltd. market a product called "Baby Cereal Twin-Pack," the wheat cereal of which does contain gluten.

THE EISENMENGER SYNDROME

OR PULMONARY HYPERTENSION WITH REVERSED CENTRAL SHUNT*

BY

PAUL WOOD, O.B.E., M.D., F.R.C.P.

Director, Institute of Cardiology; Physician, National Heart Hospital; Physician-in-Charge, Cardiac Department, Brompton Hospital, London

Distinctive Characteristics of Individual Members of the Eisenmenger Group

Patent Ductus.—(1) The catheter passed through the duct more easily than through any other central communication between the two circulations. It did so in 90% of cases, and usually took an anticlockwise course to enter the descending aorta. (2) The shunt was wholly reversed far more frequently (50%) than with other defects. (3) Patent ductus was the only lesion which was occasionally associated with no shunt in either direction. (4) Differential oxygen desaturation between right brachial and femoral samples was pathognomonic of patent ductus, and occurred in all but two cases in which there was no shunt in either direction. The oxygen saturation of samples from the right brachial artery averaged 89.6% (range 81 to 96%), and from the descending aorta or femoral artery 77.1% (range 65 to 88%).

Aorto-pulmonary Septal Defect.—(1) When the catheter passed through the defect it entered the ascending aorta from the pulmonary artery. (2) In other respects the findings were similar to those of patent ductus with bidirectional shunt but no differential desaturation.

Eisenmenger's Complex.—(1) Passage of the catheter via the defect (28%) into the ascending aorta followed a characteristic medial course as in Fallot's tetralogy. (2) An appreciable left-to-right shunt at ventricular level, as described by Bing *et al.* (1947), could be detected in all but two cases, in both of which the diagnosis was subsequently proved at necropsy. (3) Pulmonary artery samples were always between 5 and 20% less saturated than aortic or arterial samples.

Single Ventricle.—In all respects but one these cases resembled Eisenmenger's complex. The increase in oxygen saturation at ventricular level averaged 16%. The one distinctive feature was the similarity of aortic (or arterial), pulmonary artery, and ventricular samples. The arterial oxygen saturation was no lower than in other members of the Eisenmenger group, averaging 82%. Three such cases were proved at necropsy.

Transposition of the Great Vessels.—These cases also resembled Eisenmenger's complex in all major respects but one. The distinctive feature was the higher oxygen saturation of samples from the pulmonary artery compared with those from the aorta and right ventricle. In the three cases studied the difference was 32, 17, and 5%. The rise in oxygen saturation at ventricular level averaged 20%. Three cases in the series resembled Eisenmenger's complex in all respects except that the catheter took a left antero-lateral convex course as it entered the ascending aorta (Plate).

*Conclusion of the Croonian Lectures delivered before the Royal College of Physicians of London on May 15, 1958. See last week's *Journal* (p. 701) for first part.

Fig. 1, *Journal*, September 20, facing p. 709), characteristic of one type of corrected transposition. The pulmonary artery is not readily entered in such cases.

Persistent Truncus.—There were three characteristic features in the two cases studied. (1) The physiological situation was similar to that in aorto-pulmonary septal defect with the addition of a second left-to-right shunt at ventricular level. As the catheter passed from the right atrium, through the right ventricle, into the truncus, the oxygen saturation of respective samples rose first by 10 and 12.5%, and then by a further 10 and 14%. (2) The catheter entered the pulmonary arteries from the "aorta," instead of vice versa as in aorto-pulmonary septal defect. (3) Samples from the "aorta" and pulmonary arteries were identical.

Atrial Septal Defect.—(1) The catheter passed through the defect in two-thirds of 18 proved cases. (2) The pulmonary artery pressure was less than the systemic pressure by an average of 27/34 mm. Hg in 70% of the cases; in 10% it was higher; and in the remainder about the same. When mean pressures were similar the pulse pressure was usually greater in the pulmonary artery, the systolic pressure being higher and the diastolic lower than in the systemic arteries. Agents affecting pulmonary or systemic flow or resistance selectively usually altered the pressure relationship between the two circulations. (3) A direct shunt at atrial level was demonstrated in 84% of the cases, right atrial samples being on the average 13% more saturated than samples from the superior vena cava (range 6 to 21%). (4) The oxygen saturation of left atrial samples averaged 81% in the eight cases in which they were obtained (range 72 to 88). Left ventricular samples were similar when secured, and arterial samples likewise (average 82% saturated; range 70 to 88%).

Persistent Ostium Primum.—The physiological findings in four cases could not be distinguished from a combination of low atrial septal defect and ventricular septal defect, there being bidirectional shunts at both atrial and ventricular levels. The rise in oxygen saturation averaged 10% in the right atrium and 7.5% in the right ventricle. The lie of the catheter when it entered the aorta was similar in both groups to that in Fallot's tetralogy and Eisenmenger's complex.

Common Atrioventricular Canal.—A single proved case that came to necropsy had virtually both a single atrium and a single ventricle. The rise in oxygen saturation resulting from the left-to-right component of the bidirectional shunt occurred at atrial level and measured 23%. Samples from the common ventricle, pulmonary artery, and femoral artery were similar at around 80% saturated.

Anomalous Pulmonary Venous Drainage.—As a cause of the Eisenmenger reaction both total and hemianomalous pulmonary venous drainage must be rare, for no case was recognized amongst the 127 studied in this paper. One of

the additional necropsies, however, previously diagnosed as an ostium secundum type of atrial septal defect, was found to have total anomalous pulmonary venous drainage into a relatively small vein joining a locally dilated right superior vena cava. This female infant died at the age of 1 year with a pulmonary artery pressure of 105/60. No wedge pressure was recorded, but the pulmonary venous pressure must have been high in view of the small calibre of the single vein joining the superior vena cava, and this must have excited reactive pulmonary hypertension as described by Johnson *et al.* (1958) in four similar cases in which the single anomalous vein carrying all the blood from the lungs was stenosed where it joined the inferior vena cava or porta hepatis.

Dye-dilution Curves

The best method of identifying the site of the reversed shunt in Eisenmenger's syndrome is to inject a suitable dye first into the root of the pulmonary artery, then into the right ventricle, and finally into the superior vena cava, and

FIG. 10.—Dye-concentration curves from the radial artery after injecting cardio-green first into the superior vena cava, then into the right ventricle, and finally into the pulmonary artery: the double hump in the top tracing is due to the early appearance (time) of the dye when it has been injected proximal to the reversed shunt. Eisenmenger's syndrome associated with an atrial septal defect in a man aged 30.

has passed through the lungs in normal time (Fig. 10). In the case illustrated the double hump so formed appeared only when the dye was injected into the superior vena cava, proving that the reversed shunt was at atrial level.

While offering a highly satisfactory method of determining the site of a reversed shunt in Eisenmenger's syndrome, dye-concentration curves do not distinguish between individual members of each group, at least when the shunt is at atrial or ventricular level.

Angiocardiography

Selective angiocardiography may also resolve the site of a reversed shunt, and not infrequently distinguishes between individual members of each group. With atrial septal defect, for example, diiodone appears in the aorta and pulmonary artery more or less simultaneously only when injected into the superior vena cava (or high right atrium), not when injected into the right ventricle or pulmonary artery. Angiocardiography usually distinguishes patent ductus, transposition, corrected transposition, and persistent truncus from ventricular septal defect, and retrograde aortography separates aorto-pulmonary window from ventricular

septal defect (Fig. 11). Selective angiocardigrams, however, give no information about pressure, and reversed shunts are encouraged by transient overfilling of the chamber into which the contrast medium is injected; moreover, the danger of an overdose of x rays may limit the number of angiocardigrams to which a patient should be exposed, especially after cardiac catheterization. Dye-dilution curves have no such disadvantage.

FIG. 11.—Retrograde aortogram in a case of Eisenmenger's syndrome associated with an aorto-pulmonary window (with acknowledgments to Mr. Walter Somerville).

Necropsy Findings

Death occurred in 18 of the 127 cases of Eisenmenger's syndrome, and necropsy was carried out in 15 of them. Details of 38 additional necropsies of cases studied during life were sent to me by many kind colleagues in Britain, making a total of 53.

Mode of Death

The cause of death was known in 42 of these cases. Haemoptysis was the commonest natural cause, and was responsible in 29%; it was usually profuse and caused death within a few minutes, as in Eisenmenger's case. The nature of the collapse has already been discussed. Necropsy proved that the cause of the haemoptysis was usually pulmonary infarction from arterial thrombosis. In some cases, however, this was not established, and rupture of a thin-walled dilated arteriole immediately distal to the end of a thick muscular artery, as described by Dammann and Ferencz (1956) and Edwards (1957), could not be excluded. In a case described by Selzer and Lewis (1949) death was due to rupture of an aneurysm of the pulmonary artery, but this is most unusual.

Surgical repair of the defect was responsible for 26% of the fatal cases, and congestive failure for 17%; death was abrupt, presumably from ventricular fibrillation, in 14%. No other single cause, such as bacterial endocarditis, cerebral abscess, cerebral thrombosis, or pregnancy accounted for more than 5%.

Accuracy of Diagnosis

Of the 15 necropsied cases in the series fully analysed, the clinical diagnosis was wholly correct in nine, wholly wrong in two, and correct in respect of the site of the shunt but wrong in respect of the nature of the defect in four. A 40% error after full investigation is embarrassing; it was no less in the 38 borrowed cases nor in published reports in the literature. What is even worse is the high frequency of false pathological reports. The last two patients that died, for example, were diagnosed clinically as ? total anomalous pulmonary venous drainage in one case, and persistent ostium primum with bidirectional shunt

at atrial and ventricular levels in the other; the pathological reports from the hospitals where they died concluded that the first had nothing more than a simple atrial septal defect of the secundum type, and that the second had a single ventricle with intact atrial septum.

When a pathologist more accustomed to congenital heart disease examined the specimens he showed conclusively that the first had total anomalous pulmonary venous drainage into a normal right superior vena cava and the second a common atrioventricular canal with a functionally single atrium and virtually single ventricle. This is salutary experience, and emphasizes the very great care and knowledge that are needed to work out the precise physiological and anatomical situation in the Eisenmenger syndrome.

Size of the Defect

It has been stated, not infrequently, that the size of the defect is less important than the pulmonary vascular resistance in determining the Eisenmenger syndrome. This is a half-truth, for the size of the defect may very well determine the pulmonary vascular resistance. A major difficulty here is that measurements of the size of the defect vary considerably according to the circumstances under which the measurements are made. Surgical estimates in the live heart during repair work, for example, are always larger than post-mortem measurements; and post-mortem measurements are larger when made immediately after death, when the heart is fresh, than when made subsequently after the heart has been fixed. Discrepancies relating to size of defects in reported cases, therefore, are bound to arise. Nevertheless, the following statements are secure. (1) No case of patent ductus with the Eisenmenger reaction has ever been reported with a lumen less than 5 mm. in diameter. (2) No case of Eisenmenger's complex has ever been reported with a ventricular septal defect less than 1 cm. across. (3) The size of an atrial septal defect has relatively little bearing on the presence or absence of a high pulmonary vascular resistance, and varies freely between 3 and 8 cm. in both uncomplicated and pulmonary hypertensive groups.

The size of the defect in the 53 necropsies under review is given in Table VI, where it is compared with the common size of defects in uncomplicated cases as given by Abbott

TABLE VI.—Size of Communication

	Normal Resistance. Usual Range	Eisenmenger Range
Duct.	0.1 to 1.0 cm.	0.7 to 1.5 cm.
V.S.D.	0.1 to 2.0 cm.	1.5 to 3.0 cm.
A.S.D.	3 to 8 cm.	3 to 8 cm.

(1927), Taussig (1947), and Brown (1950). The figures agree fairly closely with those given for ventricular septal defect by Selzer and Laqueur (1951).

Ducts under 1 cm. across with the Eisenmenger reaction were short, and the smallest were specifically stated to have had no length. Aorto-pulmonary windows are usually large—up to 5 cm. or so in their long diameter—but probably need to be no larger than the smaller ducts, since they have no length. That ventricular septal defects averaged twice the diameter of the ducts is attributed to the fact that aorto-pulmonary shunts continue throughout the whole cardiac cycle, whereas interventricular shunts are believed to be chiefly systolic.

As pointed out by Selzer and Laqueur (1951), there is no gradual transition between a large ventricular septal defect and single ventricle. The former rarely, if ever, exceeds 3 cm. in diameter and occupies no more than 10% of the septal area in a fully grown heart; the latter has a ridge where the septum should be, but that is all. Single ventricle is always complicated by pulmonary stenosis, as in the six cases described by Campbell *et al.* (1953), or by a high pulmonary vascular resistance (Rogers and Edwards, 1951). Transposition of the great vessels may be associated, but is obviously unimportant physiologically.

Elastic Arteries

Atheroma of the large elastic arteries was common, as reported by all writers, and as originally described by Eisenmenger. Secondary thrombosis and pulmonary infarction were increasingly common after the age of 20.

Of exceptional interest is the state of the elastic fibres in the main trunk of the pulmonary artery itself. Heath (1958) pointed out that in the foetus and newborn babe these elastic fibres were long and densely packed as in the aorta. As the pulmonary artery pressure falls the fibres seem to break up, shorten, and become loosely arranged, so that they no longer resemble the aortic pattern. Heath found that sections of the pulmonary artery in Eisenmenger's complex and patent ductus with reversed shunt always resembled the foetal (or aortic) pattern, whereas in atrial septal defect with pulmonary hypertension and reversed shunt, and in all forms of pulmonary hypertension known to be acquired, the appearances were more like those in a normal pulmonary artery. He concluded that pulmonary hypertension in the Eisenmenger syndrome must be present from birth with ventricular septal defect and patent ductus, but must be acquired in atrial septal defect—at least in the great majority of cases. It should be understood that the function of elastic fibres is to prevent distension from high pressure.

Muscular Arteries

In Eisenmenger's complex pulmonary arteries with a diameter of less than 1 mm. have a thick muscular media very similar to their structure in the foetus. Civin and Edwards (1950, 1951) suggested that it was the persistence of the foetal type of muscular artery that was responsible for the high resistance, and that this saved infants with large ventricular septal defects from dying as a result of an inadequate blood flow into the aorta. In their own words, "the pulmonary vascular bed of patients with the Eisenmenger complex who survive infancy maintains its foetal function." They assumed that the thick muscular arteries of the foetus were responsible for the high pulmonary vascular resistance necessary to deflect blood from the right ventricle away from the lungs into the descending aorta via the ductus arteriosus.

Thick muscular arteries have been demonstrated also in children with a single ventricle (Edwards and Chamberlin, 1951; Heath, 1957), large patent ductus (Whitaker *et al.*, 1955), and all other members of the Eisenmenger group (Edwards, 1957).

During the first two years of life the intima usually remains normal; thereafter, however, and with varying degree and tempo from case to case, progressive intimal fibrosis develops (Edwards, 1957). This is the pulmonary vascular disease that has been regarded by some as the chief cause of Eisenmenger's syndrome—for example, Whitaker (1958). Subscribers to this hypothesis do not say how these intimal changes have come about.

Arterioles

The arterioles of the lung are vessels less than 100 μ in diameter, and consist of endothelium, a single elastic layer, and adventitia; they are not supplied with muscle. Dammann and Ferencz (1956) support Edwards in his belief that the arterioles are usually thin-walled and dilated in Eisenmenger's syndrome, and that thick-walled vessels within the usually accepted compass of an arteriole are really muscular arteries in a state of contraction, an interpretation which has been extended by Short (1957) to embrace larger arteries with thick muscular coats.

The Overriding Aorta

The following observations may clarify the position in respect of the override.

1. Ventricular septal defect is but one of a total of some 12 kinds of communication between the two circulations, all of which may be complicated by a high pulmonary vascular

resistance and reversed shunt of similar magnitude. An overriding aorta or its physiological equivalent is absent in seven of these conditions.

2. When the pulmonary vascular resistance is high the arterial oxygen saturation averages close to 80% in transposition with ventricular septal defect, persistent truncus, single ventricle, the so-called Taussig-Bing syndrome (in which the pulmonary artery is supposed to be overriding the defect in cases of transposition), and Eisenmenger's complex with or without apparent override.

3. Eisenmenger's complex with all the classical features may be associated with a defect in the muscular part of the interventricular septum as in the cases described by Weiss (1927) and Heath *et al.* (1956). There can be no overriding of the aorta in such instances.

Experimental Physio-pathology

The reaction of the pulmonary circulation in Eisenmenger's syndrome to pulmonary vasoconstrictor and vasodilator drugs seemed worth investigating.

Oxygen

In adults and in the great majority of children over the age of 5, 100% oxygen fails to lower the pulmonary artery pressure (Fig. 12) or to influence the magnitude of the shunt, as first demonstrated by Burchell *et al.* (1950).

On the other hand, breathing 10% oxygen raises the pulmonary vascular resistance and increases the reversed shunt, at least in cases with patent ductus (Burchell *et al.*, 1953).

FIG. 12.—Failure of 100% oxygen to lower the pulmonary artery pressure in a case of Eisenmenger's complex.

In infants under 2 and occasionally in small children, when intimal fibrosis in the pulmonary circulation is negligible, breathing 100% oxygen almost halves the resistance and increases the pulmonary blood flow (Edwards, 1957).

Acetylcholine

Acetylcholine, when injected direct into the pulmonary artery in a dose of 0.5 to 1.5 mg., is an ideal selective pulmonary vasodilator, for this quantity is usually inactivated by cholinesterase by the time it reaches the systemic circulation (Wood *et al.*, 1957).

FIG. 13.—Failure of acetylcholine to lower the pulmonary artery pressure in a case of Eisenmenger's complex.

When severe pulmonary hypertension was primary, or due to mitral stenosis or cor pulmonale, acetylcholine lowered the pulmonary artery pressure and resistance, and raised the cardiac output in 85% of cases (Wood, 1958). In 13 cases of Eisenmenger's syndrome, however, no such effect could be demonstrated in a single instance (Fig. 13). The youngest patient in the series, however, was 5 years old, and it is probable that infants under 2, without intimal fibrosis, would react differently. This belief is founded on the different response of these infants to 100% oxygen, as described previously, and on the fact that acetylcholine lowers the pulmonary vascular resistance sharply in the foetal lung (Dawes, 1958).

Negative reactions to tolazoline hydrochloride ("prisol") and aminophylline have also been without exception in cases of Eisenmenger's syndrome in patients over the age of 5.

Protective Effect of Stenosis

One case of aorto-pulmonary septal defect had moderate stenosis of the origin of the right branch of the pulmonary artery (Fig. 14). The pressure fell from the systemic level of 85/55 mm. Hg in the pulmonary artery to 60/40 beyond the stricture in the right branch. The nature of the defect

FIG. 14.—Pressure pulses in a case of Eisenmenger's syndrome associated with an aorto-pulmonary septal defect and stenosis of the right pulmonary artery near its origin.

FIG. 15.—Pressure pulse from right pulmonary artery beyond the stricture, showing a marked reduction of pressure following the injection of acetylcholine. The pulmonary vessels have been protected by the stenosis and are functioning normally.

was demonstrated by passing the catheter through it. When acetylcholine was injected into the right pulmonary artery the pressure fell sharply from 55/38 to 30/18 (Fig. 15). It is true that the child was also the youngest in the series investigated, being only 3 years old, but that does not alter the conclusion that vessels which are protected from extreme pulmonary hypertension, or which have not had time to develop serious intimal fibrosis secondary to the hypertension, respond briskly to acetylcholine. This disposes of the idea that there is anything fundamentally wrong with the pulmonary vessels at birth in the Eisenmenger syndrome.

This functional evidence stands solidly side by side with the anatomical observation that when the origin of the left pulmonary artery is atresic in Eisenmenger's syndrome its distal branches and muscular arteries, which are not subjected to high pressure, are perfectly normal, whereas the vessels on the other side have all the features characteristic of Eisenmenger's complex (McKim and Wigglesworth, 1954).

Similar anatomical evidence was provided by Civin and Edwards (1950) in a case of large ventricular septal defect (2.5 cm.) with marked overriding of the aorta associated with mild infundibular stenosis of the fibrous diaphragm type, the orifice being 1.5 cm. in diameter and above the level of the shunt. This man died from carcinoma of the bladder at the age of 47, and at necropsy the pulmonary vascular tree was normal.

The protective effect of stenosis is the basis of modern surgical therapy in the Eisenmenger group (Civin and Edwards, 1950; Dammann and Ferencz, 1956).

Course and Prognosis

As previously stated, the Eisenmenger syndrome is commonly established at birth or during the first two years of life when the shunt is aorto-pulmonary or interventricular, but is typically acquired when the shunt is interatrial. In the present series, for example, cyanosis dated from infancy in 80% of those with ventricular septal defect, but did not start until adult life in 92% of those with atrial septal defect. The onset of reversed shunt in patent ductus is more difficult to establish, because differential cyanosis is usually overlooked. Aorto-pulmonary septal defects, however, behave like ventricular septal defects.

The majority of those who have studied the Eisenmenger syndrome at all closely have come to the same conclusion. Thus 8 out of 13 acceptable cases of Eisenmenger's complex collected from the literature by Selzer and Laqueur (1951) dated their cyanosis from infancy, as did at least 50% of all 29 clinical cases studied by Donzelot *et al.* (1949), and all except 2 out of 20 cases reported by Kohout *et al.* (1955).

As a general rule neither cyanosis nor breathlessness changes appreciably during childhood or adolescence, but deterioration sets in sooner or later in adult life. The onset of recurrent haemoptysis may signal the downward trend, which is due in many cases to the development of thrombo-obstructive lesions.

The average age of natural death in the 18 fatal cases in this series and the 38 additional cases from elsewhere, omitting three which died in infancy, was 33 for both aorto-pulmonary and ventricular defects, and 36 for atrial septal defects. The cases in which death occurred in infancy included one severe ostium primum, one common atrio-ventricular canal with what was virtually cor biloculare, and one total anomalous pulmonary venous drainage into a stenosed vessel joining the right superior vena cava.

The maximum age reached was 65 for both the ventricular and the atrial cases, and 55 for the ducts.

The downhill course was usually punctuated with haemoptyses, which when severe sometimes caused sudden collapse and death within a few minutes, as previously described.

Bacterial endocarditis occurred in only 5% when it was responsible for death; cerebral abscess from paradoxical embolism occurred once and proved fatal; cerebral thrombosis also occurred in one case, but was not fatal. An appreciable number (14%) died abruptly, presumably from ventricular fibrillation.

As many as 26% of the fatal cases died from a surgical attempt to repair the defect, mostly from ligation of a patent ductus.

Patients who survive these risks develop congestive heart failure sooner or later, and this was the cause of death in 17% of the fatal cases.

Treatment

Medical treatment aims at preventing secondary thrombo-obstructive lesions by means of permanent anticoagulants, such as phenindione ("dindevan"). Pulmonary vasodilators, such as tolazoline, aminophylline, and reserpine, fail to lower the pulmonary vascular resistance, and do not influence the course of the disease (Rudolph *et al.*, 1958). Small venesections, repeated from time to time, may be helpful in cases with gross polycythaemia, but should be

undertaken very slowly and with the utmost vigilance. Heart failure requires the usual remedies.

Surgical repair of the defect has been responsible in recent years for more deaths in the Eisenmenger syndrome than any other agent except haemoptysis. Ellis *et al.* (1956) stated that the surgical mortality in cases with reversed shunt through a patent ductus was 56%, and Anderson *et al.* (1956), after reviewing 45 such cases in the literature, could find only four good results. Similar fatalities and poor results in the survivors are now taking place with repair of ventricular septal defect and atrial septal defect complicated by pulmonary hypertension and bidirectional shunt.

Direct repair of a defect, without the special preparation that is justified only when it can be predicted with confidence that its closure must result in a fall of pulmonary blood pressure because a hyperkinetic factor of sufficient magnitude has been eliminated. In practice this prediction can be made when the pulmonary blood flow is at least twice the systemic flow at rest, and the pulmonary vascular resistance does not exceed 10 units (800 dynes sec./cm.²). Borderline cases have pulmonary/systemic flow ratios of 1.75 to 2, and resistances of 10 to 12 units. No case with a pulmonary blood flow less than 1.75 times the systemic flow or with a resistance over 12 units should have the defect repaired in the ordinary way, whether the shunt is reversed, direct, or bidirectional.

Observance of this law since its introduction on theoretical grounds in 1950 has resulted in a mortality rate of zero for cases of patent ductus in this class. Several of them just within the limits outlined, and with samples from the femoral artery having oxygen saturations between 82 and 85%, have been cured by duct ligation. In these instances the pulmonary artery pressure fell, and the systemic pressure rose, when the duct was compressed manually. A year later the pulmonary vascular resistance was either normal or close to normal. In cases unsuitable for duct ligation identical pulmonary artery and aortic blood pressures do not separate favourably when the duct is manually occluded. Precisely the same criteria must apply to cases with interventricular or interatrial shunt.

Synthesis

The cardiac output of the newborn babe is about 0.5 l./min. (Prec and Cassels, 1955), and is presumably much the same in the foetus at term; if the situation is similar to that in the lamb, about 0.1 l./min. passes through the pulmonary circulation (Dawes *et al.*, 1954). Since the mean pulmonary artery pressure is the same as the aortic, about 50 mm. Hg at birth, the foetal pulmonary vascular resistance must be about 500 units (40,000 dynes sec./cm.²).

During the first three hours after birth a reversed shunt through a patent ductus is invariable (Eldridge *et al.*, 1954); from 3 to 72 hours after birth the shunt may be direct, bidirectional, or reversed (Eldridge *et al.*, 1954; Prec and Cassels, 1955; Amoroso *et al.*, 1958); and by the end of the third day the duct is usually closed. It follows that in newborn infants the pulmonary vascular resistance is more or less the same as the systemic—that is, about 100 units (800 dynes sec./cm.²)—for, as previously stated, the cardiac output is about 0.5 l./min., and the mean pressure around 50 mm. Hg.

Within a remarkably short time after birth, then, probably within a few minutes of independent life, a pulmonary vascular resistance around 500 units falls to about 100. Four questions clamour for an answer: (1) What is the cause of the fantastic pulmonary vascular resistance in the foetus? (2) Why does it drop so precipitously at birth? (3) Why is the rapid fall halted temporarily more or less at systemic level? (4) What is responsible for the subsequent slower decline to normal?

In the correct answer to these four questions lies the secret of the Eisenmenger syndrome.

An answer to the first has been offered by Alan Burton (1958), who points out that resistance to flow in a tube is

an adverse hyperkinetic factor, and gradual involution of the muscular pulmonary arteries.

In Eisenmenger's syndrome with aorto-pulmonary or interventricular shunt, this favourable cycle is prevented by a powerful hyperkinetic factor which maintains the pulmonary artery pressure at systemic level. So long as pulmonary hypertension is maintained vasoconstrictor tone is not inhibited and the muscular pulmonary arteries do not involute.

Obliterative pulmonary vascular disease due to reactive "endarteritis fibrosa" is secondary and is rarely found in infancy.

Thrombo-obstructive lesions are relatively late and may not be demonstrable before adult life.

The different behaviour of cases with atrial septal defect may be explained by the relatively slow involution of the right ventricle after birth. The pulmonary vascular resistance may well fall to normal before right ventricular diastolic tone is reduced sufficiently to allow a critical interatrial shunt, and, once the resistance is truly normal, flows up to 24 litres per minute do not cause pulmonary hypertension.

The practical application of these observations to the treatment of the Eisenmenger syndrome is discussed.

This analysis was begun in 1948 and two attempts at synthesis were made previously; the first in conjunction with Dr. J. B. Lowe in 1950, the second with Dr. H. Gilmour in 1953; and, though both attempts proved unsatisfactory owing to lack of sufficient data, I want to express my great indebtedness to these two colleagues.

Details of necropsies on cases well investigated during life were sent to me by Drs. I. M. Anderson, D. Evan Bedford, Wallace Brigden, Maurice Campbell, William Evans, Frances Gardner, C. J. Gavey, Ronald Gibson, Frederick Jackson, and Walter Somerville; I am very grateful to all of them for their trouble and generosity.

I would like to thank Dr. Reginald Hudson for preparing the excellent pathological illustrations at such short notice, innumerable assistants at the National Heart Hospital and the Brompton for helping with the investigations, and the technical staffs of both hospitals for their unstinted co-operation.

LOCAL TREATMENT OF BRONCHIAL ASTHMA WITH HYDROCORTISONE POWDER

BY

H. HERXHEIMER, M.D., L.R.C.P.&S.E.

Professor of Medicine, Universitäts-Asthma-Poliklinik, West Berlin

MONICA K. McALLEN, M.D., M.R.C.P.

AND

D. A. WILLIAMS, M.D., M.Sc., F.R.C.P.

Physician, Asthma and Allergy Unit, St. David's Hospital, Cardiff

The fact that bronchial asthma can be greatly improved by systemic treatment with cortisone and its derivatives is well established. This treatment, however, demands high dosage and thus has the disadvantage of causing cortical atrophy, and of other risks. Its continued use must therefore be limited to patients whose life is endangered by the asthma or where invalidism is threatening.

If a similar therapeutic effect could be achieved by local instead of systemic treatment the dosage could be expected to be much lower, and the risks connected with high dosage would be avoided. A local effect of hydrocortisone has been well known for some time in allergic disorders of the eye and of the skin. In hay-fever a similar effect has been reported more recently and has been confirmed (Herxheimer and McAllen, 1956; Godfrey, Maunsell, and Pearson, 1957; Lake, Logan, and Peters, 1957; Morris-Owen and Truelove, 1958; Findeisen, 1958). Some of these reports include a number of cases in which pollen asthma was present and which were benefited by the treatment. Apart from

these, reports on the local treatment of bronchial asthma with cortisone derivatives are scanty, and, in their conclusions, tentative only.

In this paper we report a number of therapeutic trials undertaken at different centres with the aim of contributing to this question.

Methods

Although the method of selecting patients differed in the three places of trial (London, Cardiff, and Berlin), the treatment was always the same. The patients were advised to inhale one capsule of micronized hydrocortisone snuff from a powder inhaler. A capsule containing 15 mg. of hydrocortisone and 85 mg. of lactose was placed in this inhaler; half of the contents of a capsule was inhaled orally in the morning and half in the evening. The dose of 15 mg. was chosen on the assumption that only a small part of this amount would be distributed systemically and that this part would be well below the body's own hydrocortisone production, which has since been shown to be about 14 mg. a day (Cope and Black, 1958). In many cases the patient served as his own control. In a few cases he was given hydrocortisone powder for a certain time (two weeks), followed by a similar period without powder; in most cases the hydrocortisone period was followed or preceded by an equal period of placebo snuff. In one group no attempt at control was made, and the groups of controlled patients and others will be reported separately.

The greatest difficulty was the selection of patients for the trial. Only those whose condition was a chronic one and moderately severe could be used—that is, the condition had to be fairly uniform throughout the year and severe enough to require continuous treatment. In addition, patients must have been under observation for some years, so that the variations in their condition were well known to the medical observer. Such patients are comparatively rare, as those with frequent and violent ups and downs must be excluded. Their exclusion is an absolute necessity for a trial like this, because violent spontaneous variations might be attributed to the trial substance. But even if patients are selected who conform to the conditions mentioned, there is no safeguard against intercurrent upper respiratory infections with their almost unavoidable temporary deterioration and subsequent improvement, which may mask the influence of the trial substance.

The investigation was started first at University College Hospital with the selection of a group of 12 patients, most of whom we had known for a number of years, and whose condition was stable. They were all under continuous standard treatment, usually on antihistamine drugs at night, sometimes combined with ephedrine or aminophylline during the day. As a stand-by the patients used inhalations of isoprenaline; the number of inhalations required by them during an average day and an average night was fairly constant, so that a change in the condition would be immediately reflected by a change in the number of inhalations. We were fairly confident that these patients would permit a good if provisional impression of the efficiency of the snuff. The patients in this group acted as their own controls.

The second group, containing 53 patients, was formed at Cardiff. It consisted of chronic cases—some of the allergic type and some of the infective type. Nineteen patients were controlled—that is, they had placebo capsules at some time or other, often for several periods—and 34 were uncontrolled—that is, no attempt was made to find out whether they were better or worse without the snuff. Four patients in the controlled group had only mild perennial asthma, but it became severe seasonally. All four of them were mould-sensitive.

The third group, comprising 14 patients, was selected in Berlin after some experience had been gained with the previous groups. They were chronic asthmatics of moderate severity, and in all but three its allergic character was certain.

Results (Table I)

First Group.—Five of the 12 patients were better with the snuff than without it. Their condition had improved so much that other anti-asthmatic medication was required only occasionally. In three others the improvement was moderate: the symptoms were definitely less severe, but

* "Dry" asthma.

* Relapsed after being on placebo for two months.

other anti-asthmatic remedies were still required, though not so much as before. In the remaining four the result was plainly negative. Of the five considerably improved patients, two had hypersecretion, and another, who had one of the rare "dry" asthmas, showed an extremely impressive improvement. She had been known to us for 12 years, and her history of perennial asthma with peaks in April and August had been longer. She had required frequent injections of adrenaline, these being replaced later by isoprenaline inhalations. A few years ago her condition gradually deteriorated, and she was put on maintenance doses of corticotrophin. She never expectorated any mucus except during rare and short periods of upper respiratory infection. When she was put on hydrocortisone snuff she was soon able to leave off corticotrophin and the frequent isoprenaline inhalations. At the time of writing she was free of asthmatic symptoms with 10 mg. of hydrocortisone snuff a day.

Second Group.—Of the 34 uncontrolled cases, 15 showed or reported an improvement which was judged to be moderate. Often this improvement did not last long and was followed by a respiratory infection and deterioration which took a long time to subside. As no control was possible in these cases, we do not regard them as evidence for the efficacy of the snuff. Of the 19 controlled cases, 13 showed a considerable improvement, in two the improvement was only moderate, and in four there was no improvement. The four patients with seasonal mould allergy are among those with considerable improvement. They were free of symptoms so long as they took the powder. A fifth patient with a very long history of asthma belonged to the dry type, and he also became completely symptom-free. His asthma was so severe that his chest had become deformed and his nutritional state impaired. It was most surprising to see that he no longer required any antispasmodic treatment.

Third Group.—Of the 14 patients, 10 improved considerably; five of them had no symptoms so long as they took the snuff, whilst the other five still had to use antispasmodics, though much less than before. Of the four not improved two belonged to the infective type. Only two of the improved patients had hypersecretion and continued to require potassium iodide. The patient with dry asthma improved a great deal.

Discussion

Although more than two-thirds of our patients have benefited from the treatment, the interpretation of this result requires caution. These patients were not average asthmatics, but a selected group. Many of them were selected because, according to our initial experience, they were likely to respond to the treatment. In contrast to these, the 34 patients who formed the uncontrolled part of the Cardiff experiment were unselected patients. Here the number of failures (19) exceeds the number of patients improved (15), and it is by no means certain that all the positive cases would have been proved positive if they had been in a controlled trial. It follows that this treatment cannot be expected to help the average chronic asthmatic but only certain types, and our investigation has aimed at defining these types as clearly as possible. From Tables II and III it can be seen that we have treated more allergic (33) than infective (12) cases, and that 82% improved in the

TABLE II.—Results Separated for Allergic and Infective Asthma

	Total	Improved	Unimproved
Allergic asthma	33	27 (82%)	6 (18%)
Infective asthma	12	6 (50%)	6 (50%)

TABLE III.—Results Separated for Asthma With and Without Hypersecretion

	Improved	Unimproved
<i>Patients with hypersecretion</i>		
Allergic	6 (55%)	5 (45%)
Infective	4 (50%)	4 (50%)
Total	10 (53%)	9 (47%)
<i>Patients without hypersecretion</i>		
Allergic	21 (95%)	1 (5%)
Infective	2 (50%)	2 (50%)
Total	23 (89%)	3 (11%)

allergic group as against 50% in the infective group. If we divide our patients into those with hypersecretion and those without, we find that of the 19 patients with hypersecretion only 53% improved, whereas 89% of the 26 patients without hypersecretion showed an improvement.

Although our figures are too small to permit definite conclusions, they show that the allergic type is more likely to respond than the infective type, and that the presence of hypersecretion is a handicap to the success of the treatment.

The allergic type without hypersecretion is likely to do best: there was only one failure in 22. Our experience with the three completely "dry" asthmatics is in accordance with this. The improvement of these three patients in spite of their long history was particularly impressive, because their condition was far more severe than that of the average patient in our trial. In the presence of hypersecretion, however, only half of the patients improved, whether of the infective or of the allergic type. As hypersecretion is more frequent in the infective type, the less favourable response in this type may be due to the hypersecretion. There are too few patients in the group of infective type without hypersecretion to be certain on this point.

Only a few earlier experimental observations in this field are on record. Foulds *et al.* (1955) in a preliminary communication reported an uncontrolled trial of 15 patients with hydrocortisone snuff, of whom 12 improved. Herxheimer and McAllen (1956) have observed that, in 4 out of 10 hay-fever patients who also suffered from pollen asthma, the asthma disappeared after nasal insufflation of hydrocortisone snuff, and they assumed that this was because the snuff was inhaled into the bronchi. Morris-Owen and Truelove (1958) have made similar observations. Brockbank and Pengelly (1958) reported improvement in 17 out of 24 asthmatics with hydrocortisone snuff, but prednisolone snuff had no effect in six out of seven patients. Franklin *et al.* (1958) have also reported success with topical hydrocortisone, given as a suspension, in a majority of patients. These two groups of authors do not specify the type of asthmatic patient used in their studies. For this reason it is not possible to compare our results with theirs.

Our experience shows that the result of topical treatment in any group of asthmatics will mainly depend on the type of asthma involved. Originally we had hoped that the topical treatment of bronchial asthma might replace steroid systemic therapy in most cases and might thus avoid the dangers of continuous large systemic maintenance doses. This hope has not materialized. Only a minority of patients appear to be benefited by corticoids given topically.

It is particularly disappointing that the hypersecretory type, which is normally more difficult to treat, does not respond well. The reason for this is not clear. One might think that the blockage of many bronchi and bronchioli may prevent the action of the corticoid snuff, or that the mucus covering the mucous membrane may prevent its action. If the mucus is the principal obstacle, it should be possible to achieve success by its removal or reduction. In order to test this we have attempted to decrease the hypersecretion in four severe cases by systemic prednisone, and then to replace the systemic prednisone gradually by local hydrocortisone. In three of these cases, however, this substitution was not successful: three of the patients became gradually worse on reducing systemic prednisone from 10-12.5 mg. a day to 5 mg. a day or lower, and the previous systemic maintenance doses had to be resumed. This negative outcome is in contrast to the positive result of Franklin *et al.* (1958) in six out of seven cases. However, these authors have used a prednisolone suspension and not hydrocortisone snuff in their cases, and their type of patient may have been different from ours. Further experiments will be needed to elucidate this question.

Summary

A total of 79 chronic asthmatic patients were treated with hydrocortisone powder, 45 of them in a controlled trial.

In 33 of these 45 patients a definite improvement of symptoms occurred. This improvement was seen mainly in patients with evidence of allergic aetiology and in those without hypersecretion.

Improvement was seen to a much less extent in infective asthma than in allergic asthma.

Cases of "dry" asthma responded dramatically.

We are indebted to Messrs. Paines & Byrne, Greenford, Middlesex, for ample supplies of hydrocortisone powder and powder inhalers, and for defraying some of the expenses.

BRONCHIAL ASTHMA AND CHRONIC BRONCHITIS TREATED WITH HYDROCORTISONE ACETATE INHALATIONS

BY

W. H. HELM, M.R.C.P.

AND

F. HEYWORTH, M.B., Ch.B.

From the Chest Clinic, Marsden Hospital, Burnley

Foulds *et al.* (1955) reported good results in 12 out of 15 patients with asthma who were treated with inhalations of hydrocortisone acetate in fine-particle powder. Brockbank and Pengelly (1958) and Helm and Heyworth (1958) carried out short-term controlled trials which showed that a statistically significant number of patients responded well to these inhalations as compared with the number responding to inhalations of placebo powder.

The purpose of the present paper is to record the results of two years' experience with inhalations of hydrocortisone acetate powder in patients with asthma and wheezy bronchitis and to suggest some indications for this treatment. An attempt has also been made to estimate the quantity of "inhaled" powder which enters the stomach rather than the tracheo-bronchial tree.

Material

The patients selected had all suffered from asthma or wheezy bronchitis for at least one year, and their condition had been severe enough to necessitate periods off work, except in two patients whose asthma was almost entirely nocturnal. There were 25 men and 28 women treated. The ages varied between 15 and 61 years, the mean being 40 years.

Groups and Definitions. Bronchial infection was judged to be present if the sputum contained macroscopic pus. Where necessary the pus was examined microscopically to differentiate pus due to eosinophils rather than true pus. For convenience of analysis the cases were divided into five groups: (1) recurrent acute asthma without significant bronchial infection; (2) chronic asthma without significant intermittent infection; (3) recurrent acute asthma with significant intermittent infection but little persistent sputum; (4) chronic wheezy bronchitis with significant persistent and (5) chronic wheezy bronchitis with significant intermittent infection and more than $\frac{1}{4}$ oz. (7 ml.) of sputum daily. The main difference between patients in groups 4 and 5 was in regard to the daily quantity of sputum, but infection tended to be a more prominent feature in group 5 than in group 4.

Method

All patients with significant bronchial infection when first seen were admitted to hospital for investigation and treat-

ment with antibiotics and routine antispasmodic drugs before receiving hydrocortisone inhalations, and patients whose signs and symptoms cleared completely concurrent with elimination of pus from the sputum were excluded. If the sputum rapidly became purulent again on stopping the antibiotic it was restarted and the patient remained on a small maintenance dose while starting hydrocortisone inhalations. All patients with infection were instructed to start antibiotics again should an exacerbation of infection occur while remaining on the inhalations after discharge from hospital. Patients with severe asthma (without infection) when first seen were admitted to hospital and were treated routinely with antispasmodic drugs for a few days before inhalations were given.

The patients inhaled fine hydrocortisone acetate powder from a "pabracort" inhaler, the powder being in capsules containing 15 mg. of hydrocortisone and 75 mg. of lactose powder, both being ground fine to a mean particle size of 5 microns. The initial dose varied between one capsule three times a day and one capsule daily given as half a capsule twice daily according to the severity of the wheezing at the beginning of treatment. The dose was reduced to the minimum maintenance necessary as soon as improvement occurred. Most patients were able to reduce the dose to half a capsule twice daily within the first week; this was the usual maintenance dose, although some needed to continue with two capsules daily, and some were able to reduce to half a capsule daily.

Treatment was stopped entirely in patients with recurrent acute asthma once the attack had been relieved for a week, and they were provided with capsules and instructed to restart at the onset of symptoms in a dose of between one and three capsules daily according to the severity of the attack. All patients were given any other routine treatment necessary, and this often included an antispasmodic drug before the hydrocortisone inhalation in order to facilitate deep inspiration. Those who responded well but later relapsed while continuing treatment were given prednisone by mouth in addition to the inhalations.

Patients who had failed to make any definite improvement during two weeks' treatment with inhalations were assessed as failures and the treatment was stopped.

Follow-up and Assessment of Results

The assessment of the results of treatment was made on both subjective and objective grounds. All patients had had prolonged routine treatment before starting the inhalations, and this provided a baseline from which the changes in signs and symptoms could be judged. All patients were seen by the same physician at monthly intervals or less while remaining on the treatment. Special attention was paid to the symptoms of dyspnoea and tightness of the chest, to exercise tolerance, and to the need for bronchodilator drugs. On physical examination the presence or absence of wheeze was noted and, if present, was assessed as slight, moderate, or severe on each visit.

Patients with significant bronchial infection (groups 3, 4, and 5) were instructed to bring a 24-hour specimen of sputum for inspection on each visit.

The results of the inhalation of hydrocortisone acetate powder in bronchial asthma and wheezy bronchitis are shown in the Table.

Of the 53 patients, 43 (81%) improved on hydrocortisone inhalations, whereas 10 (19%) were no better. Of the 43 patients who improved, 13 (30%) relapsed after periods of 1 to 11 months, whereas 30 (70%) maintained the improvement up to the time of writing for between two months and two years. The best results were obtained in group 1 patients with recurrent acute asthma without infection, whereas the results in group 5 patients with wheezy bronchitis were disappointing.

Complications. There were no definite complications in the present series, but one man had mild dyspepsia for a few weeks which may have been due to the hydrocortisone.

Several patients put on weight, which was probably due partly to improved health and partly to the effects of hydrocortisone absorption.

Table of Results

Group	No.	Not Improved	Improved but later Relapsed	Improved and maintained improvement to Present	Duration of Improvement in Patients	
					Relapsing	Remaining Well
1	12	1	11	1	10	9 months
2	18	3	15	5	10	2 months to 2 years.
3	7	0	7	2	4	Mean 1 year 3-18 months.
4	7	0	7	4	4	Mean 7 mths. 2-5 months.
5	9	6	3	1	2	Mean 3½ mths. 1-6 months.
Total	53	10	43	13	30	Mean 3 mths. 2 months.

Case Histories

Group 1.—A 20-year-old girl had had eczema, hay-fever, and intermittent asthma all her life. In March, 1955, she started a course of mixed inhalant desensitization, but after a short period of apparent improvement she became worse than ever in the autumn, and had three months of almost continuous wheezing which was little affected by routine measures. She was then started on hydrocortisone inhalations, and the symptoms rapidly resolved. She continued to use the inhalations on about two days out of three in a dose of one capsule daily for the next two years, and remained very much improved during this period, with only six weeks off work, compared with eight months off work in the previous two years.

Group 3.—A 37-year-old woman with no relevant family history had begun to get asthma at the age of 13. The attacks remained fairly mild and were precipitated mainly by emotion or exertion until the age of 18, when she had several years of freedom. At the age of 25 she again began to get attacks of asthma following colds and bronchitis. In November, 1956, she had a cold followed by persistent bronchitis with fever and purulent sputum; the infection finally cleared after several courses of antibiotics, but she continued to have attacks of wheezing, especially at night, and failed to respond to energetic routine measures, including antispasmodic and antihistamine drugs. After two weeks of continued night attacks with little sleep, she started hydrocortisone powder inhalations; she took one capsule in the afternoon and another in the evening. She slept well for the first time that night and had no further wheezing while carrying on with the inhalations for the next two weeks. After stopping the inhalations she remained free of asthma until a further attack following a cold one year later. This attack was again relieved by a few days of hydrocortisone inhalations.

Group 4.—A 61-year-old woman with no relevant family history had begun to have a slight cough and sputum at the age of 18. At 38 she first began to have severe wheezing attacks with no known precipitating factors; the attacks were intermittent for many years, but at the age of 58 the wheezing became almost continuous, with intermittent severe attacks necessitating weeks in bed. Finally she was confined to bed for three months with chronic status asthmaticus, and was admitted to hospital. On admission she was acutely short of breath and had a marked expiratory wheeze; she had 2 to 3 oz. (60-85 ml.) of mucopurulent sputum daily, a culture from which yielded pneumococci. She was treated with antibiotic and routine antispasmodic drugs, and, concurrent with the clearing of the pus from the sputum, she greatly improved. Two days later, however, in spite of continued penicillin and the fact that her sputum remained mucoid, she relapsed severely, with a return of severe wheezing. She started hydrocortisone inhalations in a dose of one capsule three times a day and

made steady improvement, becoming almost symptom-free at the end of a week. She continued on daily inhalations, the dose varying between one and two capsules daily, and remained greatly improved for 18 months up to the time of writing, although with considerable day-to-day variation. She continued to need antispasmodic drugs, but no further antibiotic treatment has been necessary.

Assessment of Proportions of "Inhaled" Powder

Entering the Stomach and Tracheo-bronchial Tree

It seemed certain that some of the "inhaled" powder would be swallowed whatever method of inhalation was used, since some would become arrested in the mouth, pharynx, and glottis.

An attempt was made to estimate, roughly, the relative proportions of powder entering the stomach and the tracheo-bronchial tree in two normal subjects who "inhaled" fine powder, propylidone ("dionosil"), in exactly the same manner as used for the hydrocortisone. It was hoped that a partial bronchogram might be obtained in this way, but, in spite of the fact that 4 to 5 g. of the powder was "inhaled," subsequent chest x-ray pictures showed only a few small opacities in the bronchial tree, probably due to clumping of the powder. It could be seen, however, that there was a considerable quantity of the opaque medium in the stomach of both subjects. This experiment was therefore repeated at a later date. Ryle tubes were passed and the stomach's contents aspirated, and the quantity of propylidone present was estimated. It was found that about half the "inhaled" powder was present in the stomach in each case.

Although this powder was finely ground, the experiment was hardly comparable to the hydrocortisone lactose inhalations because the propylidone was far more irritating, and necessitated considerable local anaesthetization of the throat and larynx before it could be "inhaled" at all. In addition there was a greater tendency for the powder to form "clumps." In view of these facts, three normal subjects each "inhaled" 1 g. of finely powdered lactose, having already swallowed a Ryle tube, and after drinking 4 oz. (114 ml.) of water the stomach contents were aspirated as thoroughly as possible. It was found that about 20% of the total powder "inhaled" had entered the stomach of each subject. This lower proportion was expected in view of the comparative ease of inhalation of the lactose powder as compared with propylidone.

Discussion of Results

The early results of treatment were remarkably good and many patients obtained rapid relief of wheezing, often within a few hours and after days of unsuccessful preliminary routine treatment. Once relief had been achieved, it was unusual for further acute attacks to occur for a time, provided the inhalations were continued. In the groups with chronic asthma, however (groups 2 and 4) and the group with recurrent acute asthma and intermittent infection (group 3), relapses began to occur after the first month, and became more frequent the longer the follow-up continued. These relapses were not necessarily complete, however, and some of the patients classified as having relapsed were confident that they remained better than before starting the inhalations. On the other hand, some of the patients regarded as having maintained their improvement up to the time of writing were certainly not so well at the time of assessment as they had been earlier in their treatment.

It is clear that in these groups of patients there is a tendency to relapse if treatment is maintained in the same way as was shown to occur in the Medical Research Council's (1956) trial in chronic asthma, where the advantage of patients receiving cortisone by mouth over those receiving placebo tablets rapidly diminished after the first two months until at the end of six months there was no significant difference between the two groups. In the group with recurrent acute asthma without infection however the

improvement has been maintained in all but one patient over a mean period of 10 months. All these patients have been able to stop the inhalations as soon as relief of the bouts of wheezing has been obtained and to restart at the onset of the next attack, whereas the patients with chronic asthma usually found it impossible to stop the inhalations without rapid return of wheezing, although they were able to vary the daily dose according to their symptoms.

The results were very disappointing in the patients with wheezy bronchitis (group 5), and only three out of nine improved, and the disability in these three was relatively mild. This result is not surprising, since we have found, in agreement with Moyes and Kershaw (1957), that little or no benefit is obtained in patients with chronic wheezy bronchitis and infection by the addition of oral corticosteroid drugs to long-term antibiotic therapy. It would also seem that the presence of considerable secretion in the bronchial tree is against successful local action of hydrocortisone. We have, however, treated a few very early cases, in which cough, sputum, and wheezing have been present for only a few weeks or months, with combined antibiotics and hydrocortisone inhalations with encouraging results, and it seems possible that at this stage local hydrocortisone may help in the resolution of the hypersensitive and irritable state of the bronchial mucous membrane during and after infection.

Reason for Relapse.—The reason for relapse in some of our patients who did well for a time is uncertain. It is possible that local tolerance to the hydrocortisone in the bronchial mucous membrane develops, but it would certainly not appear to be due to the development of a general tolerance to the corticosteroid group of drugs, as nine of these patients, after relapse, responded very well to the addition of a relatively small dose of oral prednisone (5 to 10 mg. daily) while continuing with hydrocortisone inhalations. One of these patients developed a gastric ulcer while taking prednisone, and, after a period of hydrocortisone inhalations only, oral cortisone (25 mg. daily) was added with maintained benefit and absence of gastric upset.

Local or General Action

Cotes *et al.* (1956) showed that there was a rise in urinary excretion of 17-hydroxycorticosteroids after the inhalation of fine particle hydrocortisone powder. This demonstrated that some general absorption had taken place, but the site of the absorption was uncertain. From our observations there would seem to be little doubt that a considerable proportion of the inhaled powder enters the stomach and is absorbed. This proportion probably varies greatly according to the condition of the patient and the technique followed by him, but is probably in the region of 20-50%. Most of the remainder must enter the tracheo-bronchial tree, and the depth of penetration probably also depends on the preceding factors. It would seem a fair assumption that some of this powder will be absorbed from the bronchial mucous membrane, and highly probable that some will be expelled by cough and cilia action and finally swallowed and absorbed from the stomach. If the dosage is large, therefore, there must be some general action from absorption of the hydrocortisone, and doubt may arise about whether or not any local action occurs.

Assuming that about 75% of the "inhaled" powder is absorbed, we can perhaps compare the results of the inhalations of hydrocortisone with those likely to be obtained by the same dose of oral cortisone, since oral hydrocortisone is recognized to be somewhat more powerful than cortisone: the starting dosages in the M.R.C. trials in chronic asthma and status asthmaticus were 300 and 350 mg. of cortisone daily respectively, and on the seventh day patients in the chronic asthma group were still receiving 100 mg. of cortisone daily, the dosage after this being left to the physician in charge of the patient. Foulds *et al.* (1955) gave 15 mg. of hydrocortisone acetate powder by inhalation daily and had good results in 12 out of 15 patients. Our starting dosage scheme was varied according to the patient's condition and the technique followed by him, but the maximum was

45 mg. daily for the first week, and the maximum maintenance dose was 30 mg. daily, the usual maintenance dose being 15 mg. daily.

The early results in our series were good in most patients, and often remarkably rapid, with relief of previously intractable wheezing within a few hours in some. We doubt whether similar results would have been obtained with a starting dose of 15 to 45 mg. of oral cortisone daily. We therefore believe that in successfully treated patients a considerable local action takes place. Further strong confirmation of this was obtained by Brockbank and Pengelly (1958), who report good results in a controlled trial using a much lower dosage of hydrocortisone powder than in the present investigation.

Indications for Hydrocortisone Inhalations

It would appear that hydrocortisone powder inhalations have most chance of maintained beneficial effect in patients with recurrent acute asthma with symptom-free intervals. In these cases the treatment can be used to break the individual attack and then be stopped, thereby reducing the chance of loss of the local effect of the powder. The results in chronic asthma are clearly not so good, for, although most of these patients improved with the inhalations for a time, relapse was more frequent, and in advanced cases the improvement did not appear to be as great as may occur with oral prednisone. However, the treatment is relatively cheap and certainly far less likely to produce severe complications; it would therefore seem well worth while trying as a first measure, since relapse does not seem in any way to jeopardize the chances of success with oral prednisone.

In patients with intermittent infective bouts followed by acute asthma, very good results can often be obtained by hydrocortisone inhalations in combination with antibiotic treatment.

Nine of our patients were seriously ill and could be classed as being in status asthmaticus at the onset of treatment, and only two failed to respond; but we feel that the ability to inhale the powder is so restricted while the extreme wheezing continues that it is probably preferable and safer to use intravenous hydrocortisone and aminophylline, or oral cortisone, or prednisone in such severely ill patients, at least until some partial relief has been obtained, when treatment could be continued with hydrocortisone inhalations with or without combined oral treatment. The two patients who failed to respond were obese middle-aged women with marked wheezing and extremely poor respiratory movements.

This treatment is unlikely to be effective in patients with advanced wheezy bronchitis, but is probably worthy of trial in combination with antibiotics in patients with symptoms of mild bronchitis which have been present for only a few weeks or months.

Summary

53 patients with asthma or bronchitis were treated for periods of two months to two years with inhalations of fine-particle hydrocortisone acetate powder.

These inhalations were found to be an effective form of treatment in many patients with bronchial asthma. There is a strong tendency to relapse if the treatment has to be maintained, but prolonged benefit may continue if the inhalations can be used intermittently for recurrent attacks of asthma.

Although this treatment may be successful in status asthmaticus, it is probably less effective in this condition than intravenous or oral corticosteroid drugs, and its use is not recommended if the patient is dangerously ill.

A considerable proportion of the "inhaled" hydrocortisone is probably absorbed, but the dosage is low compared with that used in oral corticosteroid therapy.

and the chance of toxic effect is therefore much less. The optimum dosage is uncertain, but it probably varies from patient to patient.

Little or no benefit is likely to be obtained from this form of treatment in patients with established chronic bronchitis.

We are indebted to the late Dr. W. J. Dunn, Dr. J. Shafar, and many other doctors for their co-operation; to Dr. G. Behr and Mr. H. Lawrie for carrying out the biochemical estimations; to Dr. J. Edge for helpful criticism; to Mr. E. Tallett, the hospital group pharmacist, for his enthusiastic co-operation throughout; to Mrs. J. Withnell for the secretarial work; to Messrs. Upjohn of England Ltd., who provided the material used in the early part of the series; and finally to Messrs. Paine & Byrne Ltd., who provided the pabracort inhalers and material used by most of the patients.

INHALATION OF HYDROCORTISONE ACETATE FOR BRONCHIAL ASTHMA A SHORT-TERM CONTROLLED TRIAL

BY

W. H. HELM, M.R.C.P.

AND

F. HEYWORTH, M.B., Ch.B.

From the Chest Clinic, Marsden Hospital, Burnley

The beneficial effects of oral cortisone in some asthmatic patients have been clearly demonstrated by the Medical Research Council (1956). Hydrocortisone, when given locally as a surface application on the skin or by injection into the joints and tendon sheaths, is of value in many allergic and inflammatory conditions, and when inhaled into the nose as a powder may considerably improve allergic conditions of the nasal mucous membrane, including hay-fever (Foulds *et al.*, 1955); Herxheimer and McAllen, 1956). It would therefore seem reasonable to expect a favourable response in allergic bronchial asthma if, by inhalation, sufficient hydrocortisone could be brought into contact with the surface of the bronchial mucous membrane.

Foulds *et al.* (1955) used hydrocortisone acetate in fine-particle powder for 15 patients with bronchial asthma, with encouraging results in 12. Brockbank *et al.* (1956) found no evidence of benefit in patients treated with inhalations of hydrocortisone succinate solution in a "blind" controlled trial; but in a similar trial, using hydrocortisone acetate powder inhalations, Brockbank and Pengelly (1958) report improvement in a statistically significant number of patients on the hydrocortisone as compared with a placebo powder.

The assessment of benefit from any form of "new" treatment in bronchial asthma is notoriously difficult, since so many factors, including emotion, may be important in precipitating attacks and prolonged natural remissions may occur. It is therefore desirable to submit any method of treatment to a controlled trial before a fair assessment of its value can be made.

The purpose of the present investigation is to test by a controlled trial the short-term effect of the inhalation of hydrocortisone acetate in fine-particle powder in cases of bronchial asthma.

Material and Method

The patients selected for the trial had been subject to bronchial asthma for at least one year, and with one exception the condition had been severe enough to necessitate periods off work. The exception was a patient whose attacks were almost entirely nocturnal. In no instance was the history or the state of the sputum indicative of the presence of considerable recurrent or chronic bronchial infection. Patients who had more than $\frac{1}{4}$ oz. (7 ml.) of mucoid sputum daily or who had had any previous treatment with corticosteroid preparations or corticotrophin were excluded.

The "double blind" method of trial was used and patients regarded as suitable were placed by random selection by the hospital group pharmacist into either the hydrocortisone or the placebo group. Both groups were treated by the inhalation of powder from capsules with the aid of a "pabracort" inhaler. The capsules contained either 15 mg. of hydrocortisone acetate (ground to a main particle size of 5 microns), together with 75 mg. of lactose or, in the case of the placebo, 100 mg. of lactose, also in fine particle powder. It was not felt necessary to adopt a rigid dosage scheme, since previous experience with this treatment had suggested that the number of capsules used each day probably bore no close relationship to the quantity of powder reaching the bronchial mucous membrane, and that this depended to a considerable extent on the intelligence of the patients and their ability to inspire deeply.

It was noted in this respect that no settled regime of dosage of oral cortisone was adopted in the Medical Research Council (1956) trial in chronic asthma after the first week of treatment.

The starting dose therefore varied between three capsules a day in severe cases that began the trial during an exacerbation, and one capsule a day taken as half a capsule twice daily in those beginning during a relatively mild phase. The maintenance dose was adjusted according to response, the maximum being two capsules daily and the minimum half a capsule daily. Most patients were maintained on one capsule daily. Patients were given any other routine treatment thought necessary, and where severe wheezing was present bronchial dilator drugs were used directly before the inhalation of the trial powder to facilitate deep inspiration.

In patients who remained severely ill and who had failed to improve on general treatment together with trial inhalations after several days, a "blind" change of treatment was made to the other half of the trial, the patient being unaware that any change had been made. In less severely ill patients who were progressing satisfactorily, but in whom the response was not very clear-cut, a "blind" change of trial treatment was made after one to two months.

Results

The assessment of the results of treatment was made both on subjective and on objective grounds. All patients had had prolonged routine treatment before starting the trial inhalation, and this provided a baseline from which the changes in signs and symptoms could be judged. All patients were seen by the same physician at monthly intervals or less while remaining on the trial. Special attention was paid to the symptoms of dyspnoea and tightness of the chest, to exercise tolerance, and to the need for bronchodilator drugs. On physical examination the presence or absence of wheeze was noted and, if present, was assessed as slight, moderate, or severe, on each visit. In patients with recurrent acute asthma, considerable reliance often had to be placed on the history concerning the frequency, length, and severity of the attacks before and during treatment, and a relatively longer period of observation was usually neces-

sary. The assessment of the result of treatment was made in each patient as soon as it was felt that there was adequate evidence one way or the other. The length of treatment before assessment varied between one week in two severely ill patients who had failed to respond, and whose trial treatment was therefore changed, and six months in a patient with recurrent acute asthma who continued to improve on placebo capsules. The mean period before assessment was six and a half weeks. In all patients whose trial treatment was changed, a separate assessment was made at the end of each individual trial period, and the trial remained "blind" until the second assessment had been made.

TABLE I

	Improved	Not Improved	Total
Hydrocortisone	19	4	23
Placebo	6	9	15
Total	25	13	38

The results of inhalation of hydrocortisone acetate powder and of placebo powder in 38 trial periods in 26 patients (14 men, 12 women) with bronchial asthma are shown in Table I. If the χ^2 test with Yates's correction for continuity is applied we get a value for χ^2 of 5.5, which is significant at the 2% level.

These results are perhaps open to the criticism that the treatment of 12 patients was changed from one part of the trial to the other, and that the effect of the first treatment might persist after the change had been made. The exclusion of the results of the second period in treatment in these 12 patients gives the figures shown in Table II. The value of χ^2 for these figures is 4.3, which is significant at the 5% level.

TABLE II.—Results of Inhalation of Hydrocortisone Acetate Powder and of Placebo Powder in 26 Patients (14 Men, 12 Women)

	Improved	Not Improved	Total
Hydrocortisone	14	3	17
Placebo	3	6	9
Total	17	9	26

Change of Trial Treatment

Twelve patients were changed "blindly" and without their knowledge from one-half of the trial to the other. Six of these changed from the placebo to the hydrocortisone powder; all had been no better on the placebo and one remained unchanged on the hydrocortisone; the other five made definite improvement on the hydrocortisone. Two of these patients had been very seriously ill despite energetic of these patients before the trial started and during the routine measures before the trial started and during the placebo inhalations, but both responded dramatically when changed to hydrocortisone after one week, and on the night for the change was made both slept well for the first time for many days. Six patients were changed from hydrocortisone to placebo inhalations; three of these had improved on the hydrocortisone, but the asthma had been relatively mild and the change was made in order to obtain a more clear-cut result. One of these immediately relapsed on the placebo, but the other two maintained their improvement until the trial was terminated after two and three months respectively. Two patients were not improved on either half of the trial. One man, after an initial good response to hydrocortisone in hospital, relapsed on returning home and was therefore assessed as "not improved"; he was changed to the placebo powder, on which he has remained well until the time of writing, a period of two months.

Discussion

It is unfortunate that by chance 17 patients should have been allocated to the hydrocortisone and only nine to the placebo inhalations, but we feel there is little doubt that the

inhalations have a beneficial effect for a time in some patients with bronchial asthma. The rapid improvement of five patients when changed from the placebo to the hydrocortisone was especially impressive. For success it is essential that enough powder should contact a wide surface area of bronchial mucous membrane. The powder is therefore ground fine in order to allow penetration to the small bronchioles.

Foulds *et al.* (1955) suggested that there was no advantage in the inhalation of more than 15 mg. of hydrocortisone daily. Although we have made no specific tests on these lines, the method of inhalation is so inexact, and the ability of the patients so variable in spite of careful training, that we feel this quantity may be insufficient in some patients, especially where in the initial stages of treatment chest movements are very poor and respiration is shallow owing to bronchial spasm. One of the four patients assessed as being no better on hydrocortisone, and another who improved slowly, were obese, middle-aged women with severe wheezing and distended chests who found it almost impossible to inspire deeply even with the help of preceding bronchial dilator drugs. We think that in this type of patient at least three capsules—that is, 45 mg. of hydrocortisone powder—should be inhaled daily at first to give a fair chance of success.

The disadvantage of the bigger dose is that the absorption will be higher and toxic effects more likely, and doubt may arise whether any benefit is due to local or general effects. In successfully treated patients, however, the dose can be reduced to one capsule daily (15 mg.) within a few days, and it would seem unlikely that this dosage would produce sufficient general absorption to have significant side-effects or influence on the asthma. There were no complications in the present series.

Summary and Conclusion

A short-term "blind" controlled trial of inhalations of hydrocortisone acetate in fine-particle powder has been carried out in 38 periods of treatment in 26 patients. The number of patients improved in the hydrocortisone group as compared with the placebo group was at a statistically significant level.

It is therefore concluded that hydrocortisone acetate powder inhalations are an effective form of short-term treatment in some patients with bronchial asthma.

We are indebted to the late Dr. W. J. Dunn, Dr. J. Shafar, and the many other doctors for their co-operation; to Dr. J. Edge for helpful criticism; to Dr. E. Tallett, the hospital group pharmacist, for his enthusiastic co-operation throughout; to Mrs. J. Withnell for the secretarial work; and to Messrs. Paines & Byrne Ltd. for providing the "pabracort" inhaler, and the material for the trial.

The Care of the Elderly is the report of the Ninth Conference of the National Old People's Welfare Council. This was held on April 17 and 18, 1958, in London. The conference included discussions on the future pattern of care for the elderly through health and welfare services (opening speaker, Mr. Derek Walker-Smith, Minister of Health); preparation for retirement (opening speaker, Mr. W. A. Sanderson); the housing of the elderly (opening speaker, Mr. J. R. Bevins, parliamentary secretary to the Ministry of Housing and Local Government); recruitment and training of workers among the elderly; problems of communal homes; visiting; surveys and research; and the changing pattern of comprehensive care (opening speaker, Professor R. E. Tunbridge). This report is obtainable from the National Old People's Welfare Council, 26, Bedford Square, London, W.C.1, price 3s. 6d., quoting ref. no. 534.

FOETAL CELLS IN THE MATERNAL CIRCULATION DURING PREGNANCY

BY

W. WEINER, M.D.

Director, Regional Blood Transfusion Service, Birmingham

ROSALIE M. CHILD, M.B., Ch.B.

Department of Pathology, Manor Hospital, Walsall

J. M. GARVIE, B.M., M.R.C.P., D.C.H.

Consulting Paediatrician, Manor Hospital, Walsall

AND

W. H. PEEK, M.R.C.S., L.R.C.P., M.R.C.O.G.

Consulting Obstetrician and Gynaecologist, Manor Hospital, Walsall

Levine, Katzin, and Burnham's (1941) brilliant exposition of maternal iso-immunization during pregnancy as the cause of haemolytic disease of the newborn has been vindicated in thousands of cases. Direct proof that this iso-immunization was due to an antigenic stimulus from the foetus was produced by Chown's (1954) investigation, which demonstrated foetal cells in the maternal circulation. A further paper on this subject was published by Dunsford (1957), who also found foetal cells amongst the maternal cells. In both cases the foetal cells were discovered in a blood specimen obtained after the birth of the baby. Chown's patient developed, after the usual latent period, an anti-rhesus antibody, thus making the picture complete. Bromberg, Salzberger, and Abrahamov (1956) succeeded in demonstrating foetal haemoglobin in the maternal circulation during some pregnancies, and as this could be shown not to be a normal occurrence it was also very suggestive of a "leak" in the placenta.

Case Report

A married woman aged 32 had an abortion at three months in 1953 and expected her first baby in June, 1955. Her blood group was determined on two occasions during this pregnancy as group A, rhesus negative. The serum gave no evidence of the presence of any abnormal antibodies. The baby was stillborn, but no cause for this stillbirth was found.

The patient became pregnant again in 1957, but her dates were quite uncertain; she thought that her E.D.D. was approximately mid-February, 1958, but when she attended for her first antenatal investigation on January 5, 1958, this did not seem to correspond to the clinical findings. A blood specimen gave both unexpected and unusual findings. The specimen grouped both by cell and by serum grouping as group A. However, when the cells were investigated for their rhesus group, an anti-C plus anti-D and an anti-D testing serum produced some agglutination, which to the technician seemed to be a result conflicting with our previous findings. A full investigation was therefore carried out, and this showed that both anti-C and anti-D sera produced small agglutinates "in a sea of unagglutinated cells," the typical picture of a "mixed field." Anti-E gave a negative result and anti-c almost complete agglutination. (All sera used were saline agglutinating "genotype" sera.) This investigation was repeated twice on cells from the same specimen and identical results were obtained. At the same time an investigation of the serum gave definite evidence of the presence of a low-titred blocking anti-rhesus antibody of anti-D specificity.

The presence of D-positive cells together with an anti-rhesus antibody caused us to investigate the cells for "coating," and the direct Coombs test was in fact found to be

quite strongly positive, though again a "mixed field" was noted. The specimen which had given these results was a small specimen of clotted blood, and to prepare an eluate the clot was passed through an ordinary tea sieve. The cells thus obtained were thoroughly washed and an eluate was prepared from them by the method previously described (Weiner, 1957). The eluate had typical anti-D activity when tested by means of the indirect Coombs test.

The patient was immediately written for and a further specimen was obtained (approximately eight days after the specimen described above). This further specimen, however, showed no trace of any D-positive cells in spite of the exhibition of very strong antisera. All cells were found to be rhesus negative (cde/cde). Also an indirect Coombs test with very strong blocking anti-D gave a negative result. The titre of the anti-rhesus antibody in the serum had, however, increased considerably in the meantime.

A specimen from the husband was found to be group O, rhesus positive, phenotype CcDEe (most likely genotype CDe/cDE).

From the results obtained it was concluded that the agglutinated cells in the first specimen had been derived from the baby and that these cells had been coated by a preformed maternal antibody. From the results obtained one could even predict the genotype of the baby as CDe/cde, though it was not possible to say anything about the baby's ABO group.

It was thought inadvisable to allow the pregnancy to go to full term, and a caesarean section was performed on February 8, when clinically it was thought that she was not at term. The baby's blood group was found to be A (identical with the mother's group) and to have the predicted genotype CDe/cde. The direct Coombs test was very strongly positive. Bilirubin was 7.9 mg. per 100 ml., but the haemoglobin was found at the very low level of 5.1 g. per 100 ml. The baby, a girl, weighed 6 lb. 11 oz. (3.04 kg.). Her clinical condition was very poor from the moment of birth. She was pale, grey, and oedematous. She was kept in continuous oxygen, and nikethamide was injected into the umbilical vein. An exchange transfusion was started as soon as possible. Although the exchange was smooth, it was stopped after about 65 ml. of blood had been exchanged per pound (143 ml. per kg.) body weight, because of the extremely bad condition of the baby. It was intended to repeat the procedure if her condition should show even a slight improvement after this initial exchange. However, the condition deteriorated still further, and the baby died approximately 15 hours after birth.

At necropsy a small tentorial tear, together with a large cerebral haemorrhage around the cerebellum and the base of the brain, was found. There were no effusions, the lungs were atelectatic and showed petechial haemorrhages. The liver and spleen showed the typical changes of haemolytic disease of the newborn with very active extramedullary haematopoiesis.

Discussion

Previous authors have reported foetal cells in the maternal circulation after the birth of the baby. These cells might, of course, have entered the maternal circulation during delivery, and the finding of these cells in the maternal circulation was most suggestive but not absolute proof of the presence of foetal cells in the maternal circulation during the pregnancy. We could demonstrate these cells, however, during the pregnancy and even describe their genetic make-up.

The exact date when the mother developed the anti-rhesus antibody is not known, and it is, of course, possible that it had developed after the second pregnancy—that is, before this baby was conceived. The antigenic stimulus could have been provided by the stillborn baby in 1955, similar to the cases described previously (Weiner and Hallum, 1950). We did not attempt to estimate the amount of foetal blood which had been "transfused" into the mother, as we were aware of the simultaneous presence of the maternal antibody

against them, making a quantitative assessment quite unreliable. The baby must, however, have bled extensively, as the extremely low level of haemoglobin (5.1 g. per 100 ml.) is unlikely to have been produced by haemolysis only. It seems much more likely that this low level was the result of blood loss plus haemolysis. The production of anaemia in babies through blood loss into the maternal circulation had been suggested by Wiener (1948), and we think that this case is a further example, though no doubt haemolysis played some part in the production of the anaemia.

Summary

A case of foetal blood loss into the maternal circulation is described. The foetal cells were recognized during the pregnancy in the blood stream of an immunized mother.

The maternal serum contained an anti-rhesus antibody which coated the foetal cells in the maternal circulation and gave rise to a positive direct Coombs test. It was successfully eluted from the coated cells.

We thank Mrs. June Wingham for much technical assistance.

ADDENDUM.—Since this paper was submitted a further article on transplacental bleeding from the foetus (Goodall *et al.*, 1958) has appeared.

INTRAVENOUS PHENTOLAMINE FOR PHAEOCHROMOCYTOMA AND "ADRENALINE SHOCK"

BY

R. BARRATT TERRY, M.D., M.R.C.P.

Senior Physician in Education, Division of Medical Education, Cook County Hospital; Associate in Medicine, Northwestern University Medical School, Chicago

JOHN R. TOBIN, jun., M.S.(Med.), M.D.

Senior Physician in Education, Division of Medical Education, Cook County Hospital; Assistant Professor of Medicine, Stritch School of Medicine, Loyola University, Chicago

AND

RICHARD B. O'CONNOR, M.D.

Resident Physician in Medicine, Cook County Hospital, Chicago

The management of the usual patient with phaeochromocytoma is now well established, with a welcome improvement in mortality (Kvale *et al.*, 1957). The most significant factor in this success has probably been the use of oral or intramuscular phentolamine ("rogitine") to block the effects of circulating adrenaline and noradrenaline (Iseri *et al.*, 1951; Emlet *et al.*, 1951; Newton *et al.*, 1955).

We wish to focus attention on the management of the unusual patient with phaeochromocytoma in whom the

*Known as "rogitine" in the U.S.A.

classic symptomatology of the disease is punctuated by wild unpredictable fluctuations of the systemic blood pressure with periods of alarming hypertension alternating with periods of profound shock. Such a patient has recently been under our observation, and in this instance the usual doses of phentolamine intramuscularly were found to be ineffective; however, a continuous intravenous phentolamine infusion produced dramatic improvement and, we believe, was life-saving. It enabled us effectively and leisurely to organize a programme of therapy for the operative and post-operative periods.

Case Record

The patient, an 18-year-old coloured girl, was first seen at the Cook County Hospital on January 8, 1957. She complained of nervousness, sweating, difficulty in breathing, severe lower abdominal pain, and vomiting of four hours' duration. For one year prior to admission she had had daily episodes of sweating and nervousness which began on arising and persisted until noon. Upon inspection she was seen to be orthopnoeic, grey, cold, and perspiring. The oral temperature was 101° F. (38.3° C.). The blood pressure was 80/0. The pulse was barely perceptible, with a rate of 140. The cardiac rhythm was regular. The left heart border was 3 cm. left of the mid-clavicular line in the fifth interspace. The heart tones were not unusual. Auscultation of the lungs disclosed fine and coarse moist rales throughout both lung fields. Upon palpation of the abdomen, a rounded mass, approximately 3 cm. in diameter, was detected in the left upper quadrant; it was in close proximity to the left kidney. The remainder of the physical examination showed nothing of importance.

Following palpation of the left upper quadrant of the abdomen, the patient began to tremble, her dyspnoea increased, and she sat bolt upright. She complained of a "nervousness," first in her abdomen and then "all over." This sensation was followed by increasing abdominal pain. The blood pressure was recorded as 230/17. The symptomatology suggested the presence of phaeochromocytoma complicated by acute left ventricular failure. Immediate therapy directed towards the relief of the left ventricular failure was successful. Additional therapeutic measures included sedation, complete bed rest, and elimination of all procedures which might augment tumour secretion. The patient's condition remained grave. Hypertensive-hypotensive swings in the systemic pressure continued, despite the administration of phentolamine intramuscularly in amounts of 5 mg. every four hours. For a period of 24 hours the blood pressure fluctuated between 290/140 and 80/0.

One of us (R. B. T.) suggested that phentolamine be given by continuous intravenous infusion. A solution of 30 mg. of phentolamine in a litre of 10% dextrose and water was infused intravenously at a rate of 20–80 drops a minute, depending upon the systemic blood pressure. The response was dramatic. The patient's sweating, pallor, coldness, and weakness disappeared, and within two hours she complained of hunger and was able to eat with obvious pleasure.

After surgical consultation, all agreed that the patient should be explored, but in view of her response to intravenous phentolamine there seemed to be no reason for hasty action. Two and a half days were allowed to elapse before the condition of the patient was considered to permit laparotomy. We were thus able to alert all personnel who were to be concerned with her care; and detailed check lists were prepared of all the procedures and medications necessary for proper management during and following surgery. During the 60 hours prior to surgery the patient received 250 mg. of phentolamine, and the blood pressure and pulse were recorded approximately every half-hour. Adjustments in the rate of flow of the infusion served to control all signs of tumour secretion. The patient had no symptoms, and there were no further hypertensive-hypotensive swings in the blood pressure (see Chart).

The systolic blood pressures recorded during the pre-operative period demonstrate the effect of continuous intravenous infusion of phentolamine. Also shown are the moderate blood-pressure excursions encountered during removal of the phaeochromocytoma.

Surgical premedication was by scopolamine and meperidine (pethidine) hydrochloride. The method chosen was thiopentone sodium for induction, followed by maintenance of anaesthesia with nitrous oxide through an endotracheal airway (Zintel and Bottie, 1956). Muscular relaxation was provided by an intravenous drip of suxamethonium. During induction of anaesthesia and throughout the operative period the systolic blood pressure was utilized to regulate the phentolamine infusion (30 mg. per 1,000 ml. of 5% dextrose and water). The abdomen was explored through a horizontal upper abdominal incision, and a phaeochromocytoma was found medial to the lower pole of the left kidney. The phentolamine infusion effectively controlled all hypertensive swings of the blood pressure during the period of anaesthesia induction and tumour manipulation. When the pedicle of the tumour was ligated the systolic blood pressure fell precipitously and was unobtainable for two minutes. An intravenous infusion of L-noradrenaline was started immediately (16 mg. per 1,000 ml. of 5% dextrose and water), and the hypotension was effectively controlled. L-Noradrenaline infusion in progressively decreasing amounts was continued for 12 hours post-operatively. The post-operative course was otherwise uneventful.

Discussion

Although there is ample experience to which one may refer for information concerning the management of the usual patient with phaeochromocytoma, there are few (Wilkins *et al.*, 1950; Rothermich, 1952; Gjøl *et al.*, 1957) which discuss the management of the patient in whom periods of alarming hypertension alternate with periods of profound shock. These wild swings in the systemic blood pressure are best explained if we assume that the rate of liberation of pressor substances from the tumour is inconstant. The truth of this assumption is supported by the observation that manipulation of the tumour through the abdominal wall would produce a dramatic hypertensive episode; we need not infer, however, that secretion ceases during the hypotensive episodes. Freeman *et al.* (1941) produced shock in unanaesthetized dogs by the continuous infusion of adrenaline, and the reports of Green *et al.* (1948) and Blacket *et al.* (1950) demonstrated that prolonged infusion of pressor amines was followed both in the experimental animal and in man by a period of hypotension. It is logical to assume that the infusion of pressor amines

invokes compensatory mechanisms which favour hypotension if the infusion is terminated or if the rate of infusion is abruptly diminished.

In this instance, since intermittent intramuscular phentolamine failed to control the fluctuating blood pressure, we decided to administer the drug by continuous infusion. Not only were the hypertensive episodes immediately and completely controlled, and further hypotensive crises prevented, but the patient's general clinical condition was rapidly and markedly improved. We believe that the dramatic response of the patient is a reflection of the efficacy of this approach. Many patients with phaeochromocytoma are poor surgical risks. Our results in this case suggest that the prolonged pre-operative intravenous infusion of phentolamine may be of value in the preparation of these doubtful-risk patients, whether hypertensive-hypotensive crises are present or not.

Summary

A patient with a phaeochromocytoma, in whom the classic symptomatology was complicated by wildly fluctuating blood pressure, was managed by a continuous pre-operative intravenous infusion of phentolamine over a period of two and a half days with dramatic results. The tumour was removed by surgical excision and the patient's recovery was uneventful.

The Wellcome Trustees have made a grant to the Medical Research Council of up to £26,000 for the provision of a vessel which could serve as a floating laboratory and means of transport for use by the Council's laboratories in the Gambia. On September 26 the *Lady Dale*, as the launch is named, was inspected at the boat yard of Aldous Successors Ltd., Brightlingsea, by a party from the Medical Research Council and the Wellcome Trustees. The *Lady Dale* will be based on Bathurst, at the mouth of the River Gambia, and will sail from there not only to the subsidiary field laboratories at Keneba, some 70 miles up-river, but also to other parts of the territory along the river where laboratory facilities would not otherwise be available. The research programme of the M.R.C. laboratories is concerned mainly with parasitic diseases, primarily malaria; in addition, the facilities of the laboratories, including accommodation, can be made available to visiting scientists. Formed originally after the second world war as a subsidiary of the council's human nutrition research unit in London, the laboratories are now an independent unit under the direction of Dr. I. A. MCGREGOR.

PUERPERAL MENTAL ILLNESS A FOLLOW-UP STUDY OF 75 CASES

BY

MARY E. MARTIN, M.B., M.R.C.P.I.

Assistant Medical Officer, St. Patrick's Hospital, Dublin

Mental illness occurring after childbirth is a common condition. The incidence in all confinements has been variously estimated as 1 in 400 (Boyd, 1942) to 1 in 1,200 (Morton, 1934). It is the cause of 2 to 8% of female admissions to mental hospitals all over the world (Small-admissions to mental hospitals all over the world (Small-don, 1940; Boyd, 1942; Brew and Seidenberg, 1950). What is the prognosis for recovery in the individual case? What is the likelihood of recurrence should the patient become pregnant again? Can recurrence be prevented by social, medical, or psychiatric prophylactic measures? Is termination of pregnancy indicated in any cases, and should sterilization ever be considered? This study is an attempt to answer these and other questions in the light of experience at St. Patrick's Hospital.

Material and Methods

This investigation is a study of 75 patients suffering from puerperal mental illness who were admitted to St. Patrick's Hospital, a private psychiatric hospital, between January, 1947, and June, 1957. During the 10½-year period 80 cases were admitted (2% of 4,006 female admissions) of which five could not be traced. The age of the patients ranged from 21 to 45, with an average of 31.5 years. Patients, or their relatives, were required to fill in a questionnaire giving details about their present state of health, information about all pregnancies, and the occurrence of nervous symptoms, whether associated with childbirth or not. Further correspondence and telephone calls were made in over three-quarters of the cases to elicit details from the patient and family to gain objective information from the husband or family doctor. All patients were invited to attend hospital for interview, but, as they came from all over Ireland and the follow-up period was long, a good response could not be expected. The sources of information are shown in Table I.

TABLE I.—Sources of Information

Patient	Questionnaire alone	plus letter	Total
	22	19	41
Husband	Personal interview	11	29
	Questionnaire alone	18	3
Family doctor	Personal interview	..	41
	..	..	4
Sole information from patient's questionnaire	..	..	55
Information from personal interview or family doctor	..	..	14
Information from husband	..	..	73*
Total	..	..	73*

* 2 patients had died.

In only four instances (three cases of depression and one of schizophrenia) was there no objective information about the patient's present state of health. The patients interviewed were not selected in any way, but tended to come from the Dublin area (13 of 18).

Time of Onset

In this survey all illnesses which began within six months of childbirth were included as puerperal. Some investigators in the past have taken the obstetrical puerperium of six weeks as their standard, later illnesses being termed lacic weeks. There seems to be no advantage in this. The time of onset of symptoms is shown in Table II. In 14.7% of

TABLE II.—Distribution of 75 Cases According to Time of Onset of Symptoms

	During pregnancy	0-14 days after birth	14-28 days after birth	28 days-6 months after birth
	11 (14.7%)	33 (44.0%)	12 (16.0%)	19 (25.3%)

cases the earliest symptoms were noticed during pregnancy, but there was a clear-cut exacerbation of symptoms after

confinement, necessitating admission to hospital. It must be noted that in some cases the onset of symptoms was gradual and difficult to date accurately. In many, however, it was dramatically sudden. In 60% of the cases the first symptoms were noticed within one month of delivery.

These figures correspond closely to an average of several series reviewed by Boyd. Mental illness precipitated by abortion has been excluded from this series.

Type of Illness

The cases fell into five diagnostic groups, as follows:

1. *Affective Psychosis*.—This was defined as an illness in which there is a greatly exaggerated emotional response, either depression or elation. Delusions may be present, but they are in keeping with the emotional change—for example, self-accusation or ideas of unworthiness in association with depression. Early waking and morning exacerbation of depression are often present.

2. *Schizophrenia*.—There is distorted thinking on personal topics, which are often projected as delusions or hallucinations without a corresponding emotional display (Skottowe, 1942). The affect may be one of apathy or fear, or there is incongruity of affect.

3. *Schizoaffective Psychosis*.—There is definite evidence of distorted thinking, delusions, and hallucinations characteristic of schizophrenia. In addition, there is a well-marked affective element, usually depressive with ideas of guilt, but sometimes manic. This corresponds to a group called "mixed schizophrenia" by Hemphill (1952).

4. *Toxic Confusional State*.—This was diagnosed only when two conditions were fulfilled: firstly, there was definite evidence of physical illness, such as infection of the genital tract, or breast; secondly, there was confusion, disorientation in time and place, faulty perception, amnesia, and often vivid auditory or visual hallucinations.

5. Hysteria.

The distribution of cases is shown in Table III.

TABLE III.—Distribution of 75 Cases According to Diagnosis

Diagnostic Group	Total
Affective psychosis:	
Depression	27
Mania	1
Schizophrenia	15 (20.0%)
Schizoaffective psychosis:	
Depression	24
Elation	5
Toxic confusional psychosis	2 (2.6%)
Hysteria	1 (1.3%)

The lack of standardization of psychiatric terminology, and the fact that many authors do not define their diagnostic criteria, make comparison with other series very difficult. For instance, the incidence of schizophrenia varies from 20 to 58% in reported series. The incidence of toxic confusional states has fallen over the years, owing partly to improved obstetrics and the advent of antibiotics, and partly to altered diagnosis. Cases previously called "non-toxic delirium," as described by Boyd, would now be classified as schizophrenia. Foundeur *et al.* (1957) found no cases of toxic confusional state in their series of 100 patients, though, unlike other observers, they had a high incidence (21%) of psychoneuroses. The experience in this country is that neurotic reactions, though common, rarely necessitate admission to hospital.

Treatment, Results, and Follow-up

The time interval between discharge and follow-up is shown in Table IV.

TABLE IV.—Time Interval Between Discharge and Follow-up

Diagnostic Group	4 Months-2 Years	2-4 Years	4-6 Years	6-11 Years	Total
Affective	11	8	3	6	28
Schizoaffective	3	9	5	10	27
Schizophrenic	4	3	3	5	15
Toxic confusional	1	0	1	0	2
Hysteria	0	0	0	1	1
Total	19	20	12	22	73*

* 2 patients died.

Affective Group

In this group (27 with depression and 1 with mania) electroplexy was the standard treatment. The immediate response was good in all cases. The average number of treatments given was 7.4, and the average stay in hospital was 5.5 weeks. Of the 28 patients 13 recovered with one course of electroplexy (four to nine treatments)—that is, they had lost all psychotic symptoms and their pre-psychotic personality was restored. Ten cases (including the patient with mania) relapsed within 17 days of ending the first course, but recovered after a second course. Four patients required maintenance treatments, but had all recovered within 4½ months of admission to hospital. One patient who relapsed four weeks after a satisfactory response to a course of treatment refused to return to hospital, and was still depressed five months after the onset of her illness.

Follow-up (average 2½ years after discharge) showed that 24 of the 27 were in normal health, although one had had a further puerperal depressive illness and three had had further non-puerperal illnesses, all of which responded well to electroplexy. Two patients complained of minor neurotic symptoms and one was undergoing treatment for a non-puerperal depression.

The immediate prognosis of affective disorders in the puerperium is therefore excellent and full recovery can be expected with electroplexy.

Schizoaffective Group

Of the 29 patients 28 were treated with electroplexy, and 15 of these had in addition insulin coma therapy (Sargent and Slater, 1954). The average stay in hospital was 12.8 weeks. One patient, who had severe diarrhoea, died suddenly on the fifth day after admission, probably from pulmonary embolism, but necropsy was not carried out. She had been treated with antibiotics and sedatives only. Of the 28, 18 were discharged as recovered and 10 as much improved. The latter had some residual symptoms and had not completely regained their pre-psychotic personality. However, they were considered fit to live at home and look after their family and house.

Follow-up (average 4½ years later) showed that 24 of the 28 patients were in normal health, although two had had further puerperal illnesses and one a non-puerperal psychosis, all of which again responded satisfactorily to treatment. Two patients complained of minor neurotic symptoms and one had died of pulmonary tuberculosis a year after discharge, no details of her mental state being obtainable. The remaining patient had never been completely well since the initial puerperal psychosis and had required admission to hospital for a further puerperal and non-puerperal illness. She was able, however, to live at home and look after her household.

In this group the standard initial treatment was electroplexy. If relapses occurred or if the schizophrenic element persisted when the affect was restored to normal, insulin coma therapy was given.

Schizophrenic Group

Of the 15 patients, 13 were treated with electroplexy, combined in nine cases with insulin coma therapy, in two with intensive reserpine therapy (Moore and Martin, 1957), and in one with chlorpromazine therapy. Of the remaining two patients, one was treated with reserpine therapy but later developed depression, which responded satisfactorily to electroplexy. The other had a spontaneous remission. The average stay in hospital was 12.4 weeks.

Six of the 15 patients were discharged as recovered and nine as much improved. Follow-up (average 4½ years later) showed that all 15 patients were in normal health. One patient had had a further puerperal psychosis, and one had had two further non-puerperal illnesses, all of which again responded to treatment.

These findings suggest that insulin coma therapy combined with electroplexy is a satisfactory treatment of

puerperal schizophrenia. There is insufficient experience from this study to decide whether it can be replaced by tranquillizing drugs.

Toxic Confusional Group

Both the toxic patients were febrile and obviously ill—one with a septic parotitis, the other without clear cause—and both were markedly anaemic. They were treated with antibiotics, parenteral iron, vitamins, and sedatives. One recovered uneventfully and was discharged within six weeks. The other developed depressive symptoms when all signs of toxicity had cleared up; these responded to electroplexy and she was discharged as recovered 11½ weeks after admission. Follow-up showed that both these patients were in normal health.

Hysteria: Untraced Cases

The one case of hysteria had various treatments, including psychotherapy, carbon dioxide inhalations, modified insulin, and electroplexy. She was discharged as improved after 12 weeks. Follow-up showed that she remained as previously, a very neurotic personality, but had never required further treatment in hospital.

Of the untraced cases, two had affective disorders, two schizoaffective psychoses, and one schizophrenia. All five were discharged as recovered or much improved.

In all cases, irrespective of the diagnostic grouping, simple psychotherapy in the form of encouragement, explanation, and reassurance was given in addition to the physical methods of treatment. It was considered important, too, that all patients should join in the active occupational and social therapy routine of the hospital. In some cases iron and vitamin supplements were given. The sedatives used were mostly barbiturates.

Findings at Follow-up

The psychiatric state of the whole series at the time of writing (average follow-up period, four years) is shown in Table V.

Of the 75 patients 65 are now in normal health and two have died. Two patients only have residual psychotic symptoms and it is felt that the patient who is depressed should respond well to another course of electroplexy, if she would agree to come to hospital. Five patients have residual neurotic symptoms, three of these having always had neurotic personalities. One patient is having out-patient treatment for a mild non-puerperal depressive illness. The overall picture, therefore, is very good. It is worth noting that practically all the patients who were only thought to be much improved on discharge are now considered to be recovered. Not one of 75 patients has become a chronic mental invalid.

TABLE V.—*Psychiatric State of the Whole Series*

Type of Illness	Died	In Normal Health	Residual Psychotic Symptoms	Residual Neurotic Symptoms	Under-going Non-puerperal Psychosis	Total
Affective	—	24	1	2	1	28
Schizoaffective	2	24	1	2	—	29
Schizophrenic	—	15	—	—	—	15
Toxic confusional	—	2	—	—	—	2
Hysteria	—	—	—	1	—	1
Total	2	65	2	5	1	75

It has been stated that electroplexy should be avoided for one month after confinement because of the danger of embolism from the pelvic veins during the convulsion (Jacobs, 1943; Feldman *et al.*, 1946; Brew and Seidenberg, 1950; Hemphill, 1952). Feldman *et al.* reported a death eight hours after an E.C.T. in a woman, two months after delivery, who had thrombophlebitis of one leg. She probably had had a pulmonary embolus, but a necropsy was not carried out. This is the only case of embolism following E.C.T. given during the puerperium traced in the literature. In the present study 72 patients were given electroplexy, and 12 of these started a course within four

weeks of delivery. In one patient the course was started on the third post-partum day, in six patients on the 12th to 16th days, and in five on the 19th to 24th days. There was no case of pulmonary embolism. In all cases the convulsion was well controlled with the thiopentone and suxamethonium premedication. Impastato and Gabriel (1957) describe a series of 14 patients given controlled E.C.T. uneventfully within one month of confinement.

Incidence of Puerperal Psychoses in Other Pregnancies

The details of these psychoses are shown in Table VI and VII.

TABLE VI.—*Analysis of Other Puerperal Psychoses Related to Previous or Subsequent Pregnancies*

Type of Illness	No. of Patients who had other Pregnancies	No. of other Pregnancies	No. of other Puerperal Psychoses
Affective	22	71	9*
Schizoaffective	28	87	4
Schizophrenic	12	34	2
Toxic confusional	1	3	—
Hysteria	—	—	—
Total	63	195	15

* This figure includes 2 previous illnesses in one patient—the only one in the series who had more than 2 puerperal psychoses.

TABLE VII.—*Analysis of Pregnancies Subsequent to that Associated with the First Puerperal Psychosis*

	Patients	Puerperal Illness
1st puerperal illness	75	75
1st subsequent pregnancy	44	9 (20.5%)
2nd "	23	3 (13.0%)
3rd "	9	2 (22.2%)
4th "	2	1
5th "	1	—
6th "	1	—
		15 (18.7%*)

* Calculated as a percentage of 80 total subsequent pregnancies.

It will be seen that 75 women had a total of 270 pregnancies with 90 associated puerperal psychoses—that is, for every pregnancy associated with a puerperal illness there were two normal pregnancies. After the first puerperal psychosis 1 in 5 (20.5%) of the patients had a recurrence with their next pregnancy. The overall relapse rate in all subsequent pregnancies was 18.7%.

Only six of the 11 patients who had had a non-puerperal psychosis prior to their first puerperal illness became pregnant again. They had a total of 12 subsequent pregnancies. These three again becoming ill—one on two occasions. These three all fell into the affective group. The non-relapsers comprised two schizophrenics and one schizoaffective. These numbers are too small to conclude that having had a non-puerperal psychosis in addition to a puerperal one necessarily increases the risk in subsequent pregnancies.

It has been stated that it is wise for women who have had a puerperal psychosis to avoid becoming pregnant again for two or three years (Boyd, 1942; Parfitt, 1952). Our experience does not confirm this. 37 patients had another pregnancy after their illness in St. Patrick's Hospital, and 19 of them had their baby within two years, with two associated puerperal illnesses (10.5%). The remaining 18 had babies after the two-year period, with three associated puerperal illnesses (16.6%).

Some Aetiological Factors

Personality.—Information on this subject was not sufficient for the drawing of any definite conclusions. Neurotic features were much more frequently present in the schizoaffective and affective groups than in the schizophrenic. It was noteworthy, too, that 14 of the 15 schizophrenic patients showed no clear pre-psychotic schizoid features such as unusual shyness, extreme sensitivity, or emotional coldness. This may have contributed to the excellent response to treatment in this group, for it is generally agreed that in any

psychiatric illness the chances of recovery are higher if the personality is good.

Previous Mental Illness.—In 17 patients (22.6%) there was a past history of mental illness. The corresponding figure given by Hemphill (1952) was 13% and by Foundeur *et al.* (1957) 30%. The latter found that a matched control group of patients with non-puerperal psychoses had exactly the same incidence of previous mental illness.

Family History.—There was a 32% incidence of mental illness in near relatives (grandparents, parents, siblings, uncles, aunts, first cousins). This figure is of the same order as that obtained in patients with non-puerperal psychoses, but it is much higher than that for the general population. This strongly suggests that there is a genetic element in puerperal as in non-puerperal psychoses.

Physical Illness.—13 patients (17.3%) had some form of infection during the puerperium (breast abscess, 3; infection of the genital tract, 1; abscess of buttocks, 1; urinary infection, 1; septic parotitis, 1; phthisis, 1; pyrexia of unknown origin, 5). This cannot be compared directly with the published figures from maternity hospitals, as these are assessed on the basis of a rise in temperature to 100.4° F. (38° C.) or more within 14 days of childbirth. The morbidity figures from the Dublin Maternity Hospitals in the years 1953 to 1955 vary from 0.9% to 5.6%. The considerable disparity between these figures and 17.3% suggests that infection may have played some part in the causation or aggravation of puerperal psychoses. Twelve patients (16.0%) of this series had some degree of anaemia (haemoglobin less than 11.2 g. per 100 ml.). Gatenby and Lillie (1955) found that practically 24% of antenatal patients at the Rotunda Hospital, Dublin, had a haemoglobin of less than 10 g. per 100 ml. This would suggest that anaemia was of no aetiological importance in this series. Blood W.R. was positive in 2 of the 75 patients, without evidence of involvement of the central nervous system. There were two sets of twins in the series and four stillbirths. Eight patients (10.7%) had a prolonged labour or difficult birth. Seven had a caesarean section, at least three being performed on account of nervous symptoms.

Discussion

The findings in this study may be summarized as follows. Puerperal mental illness is not a psychiatric entity, the patterns of illness being the same as those in the non-puerperal state. The prognosis in puerperal illnesses—treated as outlined—is excellent, irrespective of the diagnostic classification. It is not dangerous to give electroplexy controlled by thiopentone and suxamethonium in the first month after confinement, provided there is no evidence of thrombophlebitis. In any subsequent pregnancy there is a one-in-five chance of recurrence. There is no psychiatric basis for advising a patient to avoid having another pregnancy for at least two years after her illness. Subsequent puerperal or non-puerperal illnesses tend to be of the same diagnostic type as the original puerperal illness, and the response to treatment similar. The only definite aetiological factor is the genetic make-up, but infection may be of some importance.

Some of these conclusions are in direct contradiction to statements in other surveys, the major disagreement being on the question of prognosis in those patients showing schizophrenic symptoms. Hemphill wrote that puerperal schizophrenia was a particularly malignant illness, only one of his 19 patients recovering sufficiently to live outside hospital: "Puerperal schizophrenia, in spite of favourable prognostic criteria, is rarely curable." Skottowe stated: "In schizophrenia the prognosis is grave, few patients recovering. The most that can reasonably be expected is stabilization at a level of invalidism necessitating some special care at home; but nearly half of the patients in this group become more or less permanent mental-hospital patients, notwithstanding shock therapy." Boyd stated: "The diagnosis of schizophrenia implies a very serious

prognosis, and the majority of these patients progress to a severe mental deterioration." He felt, however, that the prognosis was slightly better than in schizophrenia occurring apart from childbirth. Brew and Seidenberg wrote: "The prognosis is somewhat poorer in the post-partum schizophrenic reactions than in these reactions in general." This pessimistic outlook is not shared by everyone, however. Mayer-Gross *et al.* (1954) wrote: "The prognosis for the first attack is relatively favourable as in other schizophrenias precipitated by physical illness." Foundeur *et al.*, from their experience with 50 post-partum schizophrenics, state: "It cannot be said that post-partum patients who were diagnosed as schizophrenic do less well than those with other diagnoses." Three out of four of their total group of 100 patients had a reasonable level of recovery four years after their hospitalization.

In view of these conflicting opinions, it is necessary to look critically at this series and at those previously published. The St. Patrick's schizophrenic group possibly comes from a better-off social class than other series. All the patients were married, and marital disharmony and home stresses, such as financial difficulties, were not much in evidence. Physical illness lending itself to correction was relatively frequent. The pre-morbid personality of the schizophrenic group was good. These factors all lend themselves to a good prognosis. In a group with a higher number of illegitimate pregnancies one would expect to find a higher incidence of unstable personalities in whom the prognosis would possibly be less good. Assessment by methods other than personal interview is open to fallacy. As the patients came from all over Ireland, and as the follow-up period was so long, personal interview with the patient was possible in only six of the 15 schizophrenic cases. In seven further cases there was information from the family doctor, and in one of the remaining two cases there was objective evidence from the husband.

Further evidence supporting the view that puerperal schizophrenia has an excellent prognosis is the fact that among the chronic female patients in St. Patrick's, the majority of whom are schizophrenics, there is no case in which the illness started during the puerperium. Moreover, it is the practice in the hospital to consider leucotomy in any illness in which a good remission cannot be obtained with other treatments, and when symptoms are persisting after two years. The records show that this has never been considered or performed in any case of puerperal psychosis. Undoubtedly before the era of active psychiatric treatment puerperal schizophrenia had a bad prognosis. This is amply documented by writers such as McIlroy (1928), James (1935), and Karnosh and Hope (1937). In those days, tuberculosis, pernicious anaemia, and many other diseases also had a bad prognosis, but the outlook has been completely changed by improvements in treatments. Modern psychiatric therapy such as electroplexy, insulin coma therapy, and the tranquillizing drugs, combined with an active social rehabilitation programme, undoubtedly does influence psychoses. Prognosis, therefore, can be assessed only in the light of the treatment given, and many authors, including Hemphill and Skottowe, give no details of intensity and duration of treatment.

There is general agreement that the great majority of patients with depressive illnesses recover, and that electroplexy is a very effective method of treatment. Hemphill, however, wrote: "There is a psychiatric entity—puerperal depression—which differs from the manic-depressive psychosis, and in many ways resembles involuntal melancholia." He believes that both puerperal depression and typical manic-depressive cases respond poorly to E.C.T., although eventual recovery is to be expected. There is no evidence from this study to support the view that puerperal depression is a psychiatric entity. Moreover, the response to electroplexy was uniformly good, although some cases pursued a relapsing course.

The only follow-up study of the prognosis in subsequent pregnancies that I have been able to trace is that of White

et al. (1957). Of their 100 patients 22 had a total of 27 additional pregnancies, but only three had a recurrence of their mental illness. They wrote: "From this small sample one might infer that the chances are that one in seven patients will experience mental illness associated with a subsequent pregnancy." Other authors give grave warnings of the dangers of subsequent pregnancies, but quote no supporting figures. Hemphill states: "It seems to be extremely dangerous for a patient who has recovered from puerperal schizophrenia to become pregnant again." Boyd concurs in a very similar phrase. The evidence from this study is that the risk of recurrence in any subsequent pregnancy is one in five. No particular diagnostic group seems more susceptible. Eight of the 15 schizophrenic patients had 13 subsequent pregnancies with only one associated puerperal psychosis. Unfortunately, no criterion by which recurrence may be forecast has been determined. Any recurrence is likely to follow the same pattern as the previous illness, and the response to treatment is likely to be similar. In the light of this knowledge no dogmatic statement can be made about the advisability or otherwise of avoiding further pregnancies. Each case must be decided on its own merits, taking into account the personality of the patient, the degree of desire for another child, and the pattern of the previous illness.

A past history of puerperal psychosis is, in the opinion of some authors, an indication for consideration of therapeutic abortion early in any subsequent pregnancy. Religious and ethical considerations forbid such a practice in Ireland. A recent discussion at the Royal Society of Medicine, London, revealed wide disagreement among psychiatrists about the value of and indications for termination of pregnancy (Pearce, 1957). The findings of this study lend no support to advocates of therapeutic abortion or sterilization. Moreover, termination of pregnancy does not seem to be without psychiatric risk. In 1955, in Sweden, where it is widely practised, Ekblad followed up a series of 479 women in whom abortion had been induced on psychiatric grounds. He found that 25% developed subsequent guilt reactions of varying severity. Siegfried (1951) is quoted as having found 59% of such reactions. Polonio and Figueiredo (1955), in a study of 244 puerperal psychoses in Lisbon, found spontaneous abortion responsible for 20% of the cases.

It would seem wise, in the individual case presenting early in a subsequent pregnancy, to inquire about marital stresses and home difficulties which might be alterable. Efficient antenatal care should be ensured, to minimize infection and anaemia. Encouragement and reassurance will often be necessary. Four patients in this series developed anxiety symptoms during ensuing pregnancies. These responded well to simple psychotherapy and mild sedation.

The conflicting views about psychoses associated with childbirth can be resolved finally only when large-scale studies with careful and personal follow-ups are undertaken. It would seem to be an eminently suitable and worth while subject for a Medical Research Council investigation co-ordinating the facts from a number of centres.

Summary

75 patients who had suffered from puerperal mental illness were followed up for periods varying from 4 months to 10½ years. Diagnosis, treatment, and results are analysed.

65 of the patients are now in normal health and only 2 have residual psychotic symptoms. None have become chronic hospital invalids. All 15 schizophrenic patients are fully recovered. The diverse views on the prognosis in puerperal schizophrenia are reviewed and discussed.

Electroplexy controlled by relaxants was given uneventfully to 12 patients within one month of confinement. It is considered to be safe, provided there is no evidence of thrombophlebitis.

The recurrence rate of puerperal mental illness in subsequent pregnancies in this series was 1 in 5 (18.7%). Relapse was not more frequent when the next birth occurred within two years of the illness.

Therapeutic abortion is discussed.

I thank Dr. J. N. P. Moore, medical superintendent of St. Patrick's Hospital, for helpful advice and permission to publish. I am also grateful to Dr. E. A. Martin, physician in charge of clinical research, for much help and constructive criticism.

ACUTE LARYNGOTRACHEOBRONCHITIS TREATED WITH 0.125% SUPERINONE

BY

M. HOLMES-SIEDLE, M.B., B.Ch.

House-Physician, Oldchurch Hospital, Romford, Essex

AND

T. N. NAUTH-MISIR, M.B., M.R.C.P., D.C.H.

Paediatrician, Oldchurch Hospital, Romford, Essex

0.125% superinone is a surface-active agent which acts by lowering surface tension, causing liquefaction of thick mucoid and purulent exudations in the upper respiratory tract and bronchial tree. Thickening of the sputum and dryness of the respiratory membranes are minimized, permitting better ciliary action and thus facilitating expectoration. Superinone is made up in a sterile alkaline medium ("alevaire"), which is administered as an inhalation in the form of a fine mist produced by a nebulizer usually activated by oxygen. It may be given intermittently or continuously (see illustration).

Acute laryngotracheobronchitis is usually of sudden onset and often follows a mild upper respiratory infection. It may be rapidly fatal, death being due either to asphyxia caused by laryngeal obstruction with thick viscid mucus or to toxæmia. The infection is probably of virus origin (Rabe, 1948). Cytopathogenic agents have been isolated from the secretion of several patients (Beale *et al.*, 1957), and in a recent paper Beale *et al.* (1958) demonstrated that the presence of these bodies in cases of acute laryngotracheobronchitis is associated with a rise in antibodies during convalescence. Clinically the appearances are reminiscent of laryngeal diptheria (Garson, 1950), and before the name laryngotracheobronchitis was coined many cases were thought

to be due to this cause, though this diagnosis was never confirmed at post-mortem examinations.

The advent of chloramphenicol was of great value in dealing with the infection and toxæmia (Moncrieff and Weller, 1949), thus reducing the mortality; but the treatment of the asphyxia proved more difficult. Mild cases may be treated by steam inhalation if there is no evidence of bronchopneumonia, but as the patients are anoxic oxygen must be given as well. These patients

Apparatus for administering alevaire in a fine mist.

were therefore nursed in an oxygen tent, being transferred to a steam tent for 10 minutes every hour. Pharyngeal suction was carried out every 15–20 minutes. For cases with asphyxia bronchoscopic suction seemed rational, but this was not always possible and the manipulations involved could easily prove fatal. Tracheotomy then was the only means of trying to prevent death from asphyxia, but, although this successfully bypassed the obstructed larynx, one still had to deal with the viscid exudate in the trachea and bronchial tree. It was felt, therefore, that 0.125% superinone might be of use in dealing with this exudate, and the following is a report of five cases so treated.

Case Reports

Case 1.—A female infant aged 6 weeks was admitted to hospital on February 6, 1958, with a 24-hour history of a cough and cold. She had become very pale and short of breath in a few hours. The birth, personal, and family history revealed nothing relevant. On examination she was afebrile, but grey, cyanosed, and distressed, with rapid breathing and some subcostal recession. Air entry was good, with crepitations at the right base. Post-nasal mucus in small quantity was present. Penicillin was prescribed and the infant nursed in an oxygen tent. She became very much worse some 12 hours later, with marked respiratory embarrassment, collapse, and cyanosis. Air entry over the

lungs was then very poor and there was much white viscid mucus in the fauces arising from the larynx. A diagnosis of acute laryngotracheobronchitis was made. It was decided to give alevaïre by facemask for 10 minutes every two hours, followed by pharyngeal suction. Penicillin was discontinued and chloramphenicol 125 mg. six-hourly substituted. After 12 hours there was no dyspnoea or cyanosis, and mucus was much reduced and less viscid. Air entry was then good, with no subcostal recession. The alevaïre was finally discontinued after 48 hours and the oxygen tent removed. Chloramphenicol was stopped after five days. On admission the W.B.C. was 16,300. The chest x-ray picture on February 20 was clear. The baby was discharged quite well after 18 days.

Case 2.—A female infant aged 3 months was admitted to hospital on February 11, 1958, with a history of croupy cough for 24 hours. She became worse suddenly two hours before admission, with marked dyspnoea and cyanosis. The birth, personal, and family history revealed nothing relevant. On examination she was afebrile, collapsed, and limp, with moderate generalized cyanosis, much dyspnoea, and moderate subcostal recession. Faucial examination revealed much viscid white mucus arising from the larynx. Air entry was poor and few crepitations were heard. There were no other significant signs. Acute laryngotracheobronchitis was diagnosed and she was admitted to hospital at once. The infant was nursed in an oxygen tent and was given alevaïre by facemask for 10 minutes every 90 minutes, followed by pharyngeal suction and chloramphenicol 125 mg. six-hourly. After 12 hours there was no dyspnoea or cyanosis, and the fauces were clear; the air entry over the lungs was good, with no subcostal recession. Her general condition was very good. Alevaïre and the oxygen tent were discontinued after 48 hours and chloramphenicol after five days. The W.B.C. on admission was 8,400. The chest x-ray picture on February 19 was clear. The infant was discharged after 19 days in excellent general condition.

Case 3.—A male infant aged 3 weeks was admitted to hospital on February 17, 1958, with a three-day history of cough and 12-hour history of cough with vomiting and cyanosis. Birth, personal, and family history showed nothing relevant. On examination he was afebrile and slightly cyanosed, with rapid respiration and marked subcostal recession. Air entry over the lungs was poor, and there was inspiratory stridor. A moderate amount of white viscid mucus was present in the throat. The infant was nursed in an oxygen tent and was given alevaïre by facemask for five minutes every two hours, followed by pharyngeal suction and chloramphenicol 125 mg. six-hourly. The patient showed marked improvement in about eight hours. There was no dyspnoea or cyanosis, the fauces were clear, and air entry was good. The oxygen was discontinued after 24 hours, but chloramphenicol was continued for five days, by which time all abnormal signs had cleared. The W.B.C. on admission was 7,600. The baby was discharged after 11 days.

Case 4.—A male infant aged 4½ months was admitted to hospital on March 1, 1958, with a history of cough and snuffles for two weeks and pallor and cyanotic attacks for two days. A dyspnoeic attack occurred before admission. Birth, personal, and family history revealed nothing relevant. On admission the child was febrile, with only slight cyanosis and normal respiration, and did not appear to be seriously ill. Air entry over the lungs was good, with a few crepitations at the left base. A short time after admission, however, he became very distressed, pale, cyanosed, and limp. On examination there was very poor air entry with marked respiratory embarrassment. Faucial examination revealed a large quantity of viscid white mucus. Treatment consisted of immediate pharyngeal suction. Alevaïre was given by facemask five minutes every two hours followed by pharyngeal suction, and chloramphenicol 125 mg. six-hourly was prescribed. There was marked improvement after about 12 hours: no dyspnoea or cyanosis, air entry good, and fauces free of exudate. The alevaïre was discontinued after 36 hours, but the oxygen tent was needed for three days.

Chloramphenicol was stopped after five days. Progress was complicated by a secondary bronchopneumonia, which, however, responded to tetracycline. Chest x-ray films showed a patch of consolidation at the right base which suggested abscess formation, but further films showed that this was resolving satisfactorily. This, of course, has prolonged the baby's stay in hospital. The W.B.C. on admission was 7,300.

Case 5.—A male infant aged 5 weeks was admitted to hospital on March 1, 1958, with a three-day history of cough and cyanotic and dyspnoeic attacks for the previous few hours. Birth, personal, and family history revealed nothing relevant. On examination he was cyanosed and dyspnoeic, with marked subcostal recession. Air entry over the lungs was very poor; there were no added sounds. A moderate amount of viscid white mucus was present in the pharynx. He was nursed in an oxygen tent and given alevaïre by facemask for five minutes every two hours followed by pharyngeal suction and chloramphenicol 125 mg. six-hourly. Marked improvement occurred after a few hours: improved air entry, no dyspnoea or cyanosis, and fauces free of exudate. Alevaïre was discontinued after 36 hours; oxygen was maintained for three days. Chloramphenicol was discontinued after five days, by which time all abnormal signs had disappeared. The W.B.C. on March 4 was 17,800. Chest x-ray examination on March 12 showed clear lung fields with some interlobar pleural thickening on the right side. He was discharged quite well after three weeks.

Comment

Cases 1, 2, and 4, would have qualified for tracheotomy, but it was decided to try the effect of alevaïre before actually resorting to this. Previous attempts at diffusing alevaïre into the oxygen tent continuously had not been successful, so it was thought advisable to administer it in Case 1 by means of a facemask placed directly over the patient's nose and mouth. The resulting liquefaction of the thick viscid mucus after only a few minutes, with rapid improvement of the asphyxia and cyanosis, was quite impressive, and so this method of administering alevaïre intermittently was continued. Although the laryngotracheal secretion ceased to form after 8 to 12 hours, the intermittent administration of alevaïre was continued for a longer period as described in the case reports.

Summary

Five cases of acute laryngotracheobronchitis are reported in which the asphyxial aspect was successfully treated with alevaïre. Three of these (Cases 1, 2, and 4) would have needed tracheotomy otherwise. The alevaïre resulted in rapid liquefaction of the viscid laryngeal exudate, with immediate improvement of the dyspnoea and cyanosis. All the patients recovered.

We thank the sisters and nursing staff for the excellent nursing management of these cases.

ADDENDUM.—Since the above was written Case 4 developed a recurrence of bronchopneumonia during his convalescence. His stools were then noticed to be frequent and very offensive. Examination of the stools showed no tryptic activity. No tryptic activity was detected in the duodenal juice, and his sweat test showed an increase in the chlorides to 840 mg./100 ml. There seemed no doubt, therefore, that he was suffering from mucoviscidosis. His condition continued to deteriorate, with increase in the physical signs over the lungs and reticular shadows in the chest x-ray films. Death occurred on April 25, 1958. Post-mortem examination revealed purulent bronchopneumonia and a tough fibrotic pancreas.

POISONING BY ACONITINE

REPORT OF TWO CASES

BY

F. S. FIDDES, M.D.

Department of Forensic Medicine, University of Edinburgh

The history of poisoning by aconite is a long one, going far back into ancient times. This is not surprising, since the plant species from which the poison is derived, notably *Aconitum napellus* (monk's-hood) and *Aconitum ferox*, are common and widely distributed. Within modern times, however, aconite poisoning has been relatively uncommon, certainly within the United Kingdom; and poisoning with the pure alkaloid itself, aconitine, is still more rare. For this reason the symptoms are worth recording, as they occurred in two recent non-fatal cases.

Two medical students, engaged in "spring-cleaning" a privately owned collection of materia medica, found in one of the cupboards a number of small glass phials labelled as containing various vitamin preparations. These they decided to throw out, but before doing so they each took a "pinch" from certain of the phials, including one from which a detached label, inscribed "vitamin C" appeared to have fallen. Subsequent investigation showed that the white crystalline powder in this phial was in fact aconitine, in a total quantity of about 250 mg. (4 gr.), but failed to reveal how the aconitine came to be in the collection or how long it had been there.

In an attempted assessment of the amount they had had, the students demonstrated exactly how they had taken a pinch of powder between finger and thumb, put it on the palm of the other hand and then transferred it to the tongue. Although an estimate arrived at in such a manner cannot be regarded as exact, it is based on more direct evidence than is available in many cases of poisoning, and the students' statements and demonstrations were consistent and convincing. From these it appears reasonably certain that each student had a dose of between 5 and 10 mg. (1/12–1/6 gr.) of aconitine, and more nearly the latter than the former. Both agreed that there was no great difference in the quantity of powder taken, but that Mr. B. (Case 1) probably had slightly more than Mr. T. (Case 2).

The aconitine was taken at 1.20 p.m., and the following is a description of the subsequent symptoms in each case.

Case 1

Mr. B. experienced a "sharp," slightly bitter taste, and a rapidly developing sensation of warmth and tingling in his tongue, which increased in intensity and extent until his whole mouth was affected. Within 10 minutes his tongue, cheeks, and lips felt numb and "drawn," his throat felt constricted, and he had a feeling of nausea. He gargled with water and took a large drink of water to make himself vomit. In this he was successful, and vomiting recurred at intervals during the next four hours without any further efforts on his part. Within half an hour of taking the dose, tingling and numbness had appeared in his fingers, and gradually spread "all over," but became particularly noticeable and distressing in his jaws and face. The vomiting, tingling, and numbness increased to a maximum about 4 p.m.—that is, some two and a half hours after taking the poison, and at this time he was conscious also of great tiredness and actual muscular weakness, so marked that he could only lie on his bed. In spite of his tiredness, however,

he felt restless, the restlessness being attributable at least in part to a feeling that the sensory disturbances in the face and elsewhere were more distressing if he stayed still. From 4 p.m. onwards his symptoms abated gradually, and by the later part of the evening he felt quite fit and well again.

Case 2

Mr. T. experienced almost immediately a slightly bitter taste and a tingling, burning sensation in the tongue, mouth, and throat, which developed into a condition of numbness, tightness, and constriction, lasting till 2 p.m. At 2 p.m. he felt slight nausea and was salivating freely but did not vomit. Indeed, during the next hour his symptoms regressed and he felt fairly well. At 3.15 p.m., however, he began to experience a tingling sensation, which gradually pervaded all parts of the body, becoming especially marked in the face. By 5 p.m. this tingling and numbness in the face were very distressing; he had had three bouts of retching and vomiting; he felt very sick and salivated freely; he felt faint and very cold, especially in the limbs, and his voice seemed far away. His skin was cold and moist.

He had to lie down because he was so weak, and he could scarcely move his limbs. Voluntary effort to seek or call for assistance was impossible. Yet he felt restless, and again the restlessness was dictated in part at least by the feeling of apprehension induced by the numbness in his face, and elsewhere, which seemed to be worse when he lay still. Any attempt to get up, however, brought him near to fainting. He remained in this state for more than two hours, the symptoms of tingling and numbness, salivation, and sickness, coldness, and faintness, weakness, restlessness, and a feeling of dread all persisting and becoming even worse. During this period he repeatedly tried to feel his pulse, but it was undetectable. His illness reached its climax between 7 and 8 p.m., and from 8 p.m. onwards he improved gradually. About 11.30 he fell asleep. He slept soundly throughout the night and felt quite recovered the following day.

Comment

It will be recalled that Mr. B. had, if anything, a larger dose than Mr. T. From the relative severity of their illness it would appear probable that Mr. B. succeeded in getting rid of a proportion of the poison by means of his self-induced vomiting 10 minutes after the dose was taken and by the further attacks of vomiting soon afterwards. Mr. T. did not take the same precautions, nor did he have any vomiting for the first two and a half hours or so. Indeed, he was lulled into a false sense of security by the almost complete absence of symptoms between 2 and 3 p.m.

Neither student received any treatment, although they reported to the out-patient department of a hospital about 2 p.m. They were told to go home, lie down, keep warm, and return if they felt worse—sound enough advice so far as it goes, and perhaps reasonable in the circumstances at that time, although in the light of events it might well have been supplemented or replaced by more active measures and a period of observation. The students went from the hospital to their respective lodgings, where, as it happened on that particular day, they were obliged to endure in solitude what was, particularly in the case of Mr. T., a most unpleasant and alarming experience.

Identification.—The powder in the phial was submitted for chemical investigation. It was reported as being purely alkaloidal in character, and giving reactions which were consistent with its being aconitine. With the usual range of chemical tests for alkaloids it is not possible as a rule to be more specific than this when seeking to identify aconitine, and confirmation must be sought by means of physiological tests. The substance was personally sampled, perhaps slightly to excess, for not only was there a rapid development of warmth and tingling in the tongue and mouth, but this went on to numbness and tightness of the mouth and throat and tingling in the fingers, which persisted for some time. Finally a dose of 0.5 mg. (1/128 gr.) was injected

subcutaneously into a rat. After a delay of about a minute, the animal showed signs of restlessness and agitation, and started to run. Salivation, retching, and respiratory distress developed, followed by paralysis, affecting first the hind limbs and then the forelimbs. There were terminal convulsions before the animal died three minutes after being given the injection. These were the results on which the opinion was based that the material in the phial was in fact aconitine.

Discussion

The fatal dose of aconitine is variously stated as being anything from 1/60 to 1/10 gr. (1 to 6.5 mg.) or slightly more. The uncertainty on what constitutes a fatal dose is no doubt related to the infrequency of poisoning with the pure alkaloid and also to its unstable nature. Furthermore, there are several varieties of aconitine, and they are not all equally poisonous. Factors of this kind presumably explain why the results were not even more serious in the cases described, although in each case the dose was certainly in excess of that which is commonly regarded as fatal or potentially so.

Aconite (aconitine) has both a local or peripheral and a systemic or central action, and both have served as a basis for its use as a therapeutic agent. The local or peripheral effect is the more striking and characteristic—namely, tingling and numbness, experienced either on local application or in the mouth when ingested, and in the extremities after absorption. The drug was formerly used, usually in the form of the tincture, for the relief of neuralgic or rheumatic pain. The central effect of value was believed to be a slowing of the heart and a reduction in blood pressure, hence its former use in certain cases of heart disease and in various febrile conditions.

To-day aconite is very little used therapeutically, and never internally, except perhaps in homoeopathic practice. Aconite poisoning is therefore uncommon, and the occasional cases which do occur are usually due to the suicidal or accidental ingestion of a liniment containing aconite mixed with other noxious substances. Accidental death through mistaking monk's-hood root for horse-radish is less frequent to-day than it appears to have been some years ago.

Because of its rapid and rather striking local effects, aconite is not an ideal homicidal poison, and it has rarely been used as such in this country. It has been suggested, however, that because of the effects on the heart, coupled with peripheral effects experienced in the arms and hands, sickness, and upper abdominal discomfort, and an early fatal outcome, cases of homicidal aconite poisoning might well be overlooked and regarded as deaths due to coronary artery disease.

In an Irish case in the first half of last century (*Regina v. McConkey*, 1841), powdered aconite root (monk's-hood) was mixed with pepper and sprinkled over the greens which formed part of the victim's dinner. Dr. Pritchard (1864-5) gave tincture of aconite mixed with Battley's solution to at least one of his two victims, but essentially the deaths were due to antimony poisoning. The outstanding homicidal case is undoubtedly that of Lamson (1881-2), also a medical man of sorts, who administered the alkaloid aconitine in a capsule (or a cake) to his invalid brother-in-law.

In the Lamson case aconitine was detected in the vomit, in the urine, and in an extract from the stomach, stomach contents, liver, spleen, and one kidney. Identification was by means of alkaloidal reactions, by the local effects produced on the tongue, and by the rapidly fatal effects on mice. Since then various colour and crystal tests have been described in attempts to render the chemical identification of aconitine more positive, but there is no general agreement on the specificity of any such tests. It has been suggested that most reliance can be placed on the effects of aconitine on the frog's heart, which appear in a characteristic sequence—namely, initial slowing followed by sudden acceleration, then incoordination, and a final slowing and arrest.

Greater certainty may be possible with the more modern methods of chromatography and spectrophotometry. Curry and Powell (1954) have described a method for the detection of alkaloids on a micro-chemical scale by means of paper chromatography which would appear to be applicable in the case of aconitine. Similarly, Kaye (1954) has described a characteristic spectrophotometric absorption curve for aconitine. Since these methods are applicable to very small quantities of material they would, if proved to be sufficiently specific, provide an extremely valuable means of identification, and might indeed relegate the older forms of testing to a role which was largely confirmatory. It is certain, however, that the characteristic and striking local effects of aconite will always retain their highly diagnostic significance.

Medical Memoranda

A Case of Nephrogenic Diabetes Insipidus

Nephrogenic diabetes insipidus is a heredo-familial disease characterized by polydipsia and polyuria from infancy. It is a sex-linked condition affecting males usually and transmitted by females, who act as heterozygous carriers. The condition is resistant to treatment with "pitressin," and appears to be due to an inherent kidney defect which results in failure of tubular reabsorption of water. Renal function in all other respects is unaffected. The following is a report on a case occurring in a youth of 18. This case is of interest because some of the female members of his family, besides acting as carriers, appear to have suffered from the full-blown clinical syndrome.

CASE REPORT

The patient complained that he had had to drink large quantities of water and passed large amounts of "white urine" for as long as he could remember. He found it necessary to carry supplies of water with him on train journeys or when he visited the cinema. Failure to relieve his thirst resulted in drowsiness, headache, and general malaise. He passed urine every half to one hour during the day and four to six times during the night. His daily intake and output was between 12 and 16 litres of water.

He was one of 10 children who were all alive except one brother who died at birth. He had five living brothers and three sisters. His mother, eldest brother, a maternal aunt, a maternal uncle, a female cousin, maternal grandmother, a maternal great-uncle, and maternal great-grandmother all suffered from this syndrome from birth. The family tree showing the incidence of the disease in the two sexes was compiled from information given by the patient and his mother. The latter stated that she found it necessary to take 6 pints (3.4 litres) of water to bed with her at night and drank much more during the day. The general appearance of the patient was normal and there were no abnormal physical signs in any system.

Special Investigations.—The specific gravity of the urine varied from 1000 to, on one occasion, 1012. More usually it was between 1004 and 1008. It was not possible to carry out a urine concentration test, as the patient could not be deprived of water for a sufficient length of time. M.S.U.: reaction acid; protein nil; reducing substances nil; deposit N.A.D.; cultures sterile. The blood urea was 32 mg./100 ml. Serum electrolytes were within normal limits. X-ray films of the chest and skull were normal. The Wassermann, Kahn, and Price precipitation reaction were negative.

At first twice-weekly injections of 5 units of pitressin in oil were given intramuscularly. This, however, had a negligible effect in reducing the polyuria. The patient did feel that pitressin snuff administered four or five times daily reduced his frequency slightly, but this was not enough to render its continued use worth while. It can be concluded, in this case, that pitressin by the intramuscular or nasal route had no appreciable effect in reducing diuresis.

COMMENT

This case is of interest in that females appear to have exhibited the fully developed clinical syndrome. This feature is unusual. Recent published work has shown that symptomless female carriers of the disease show an impairment of urine-concentrating power and a lowered response to pitressin (Garrod, 1956). Carter and Simpkins (1956) investigated four families and showed that the female carriers were unable to concentrate urine beyond 1018. They suggested that this test be used as a means of "carrier state" detection.

My thanks are due to Lieutenant-Colonel R. M. Johnstone, R.A.M.C., for his kind permission to publish this case.

Duplication of the Stomach Simulating Pyloric Stenosis

Duplication of the stomach is an uncommon condition. Gross (1953) reports two cases in a series of 68 duplications of the alimentary tract studied by Dr. Sidney Farber at the Boston Children's Hospital. One, in a child of 7 years, gave a palpable mass in the epigastrium, but did not produce obstruction. The cyst was as large as the stomach, and lined by necrotic mucosa. Treatment by partial excision and by marsupialization was successful. His second patient, aged 3 days, had a cyst 4 cm. in diameter, lined by gastric mucosa, on the greater curvature of the stomach. Excision of the cyst and gastrostomy were performed, but the baby died. Galloway, Sutherland, and Williams (1956) report a case, first seen at the age of 4 weeks, with symptoms of vomiting, green slimy stools, and failure to gain weight. A swelling was visible in the left hypochondrium moving downwards when the baby was fed. Peristalsis was not seen. The vomiting was not severe, and operation was postponed until the baby was 4 months old. The cyst measured 5 by 3 by 3 cm., and was attached midway along the greater curvature. It was lined with gastric mucosa. Complete excision of the cyst was carried out and the baby made a good recovery.

The following case presented with symptoms and signs suggesting pyloric stenosis.

CASE REPORT

A male child, the second baby of healthy parents, was born on September 22, 1956, by caesarean section, and weighed 10 lb. 3 oz. (4.6 kg.) at birth. He was breast-fed for the first month and did not vomit during this time. At the age of 4 weeks he was put on to feeds of full-cream National dried milk, and a week later he started to vomit about half of every feed. The vomits were projectile in character, and he became constipated. On admission to hospital on November 17, at the age of 8 weeks, he weighed only 8 lb. 13 oz. (4 kg.).

On examination he was thin and slightly dehydrated. His stomach contained 1 oz. (28 ml.) of residue immediately before a feed. During feeding visible gastric peristalsis was seen, and a large firm mobile tumour was felt in the right hypochondrium. He was given small frequent feeds of half-strength Hartmann's solution, which he retained. His dehydration was corrected, and he was fit for operation on November 19.

Operation was performed by Mr. A. C. Gairdner. The pylorus was found to be normal. The pyloric antrum was obstructed by a pyriform swelling which formed part of the

Operative findings. A=Stomach. B=Duplication. C=Pulsion diverticulum. D=Transverse colon. E=Gastrocolic omentum.

greater curvature of the stomach. This swelling had a common muscular wall with the greater curvature of the stomach, and was a blind gastric duplication consisting of secreting gastric mucosa and muscular tissue which was grossly hypertrophied. The wall common to the stomach and the swelling was also grossly hypertrophied, and it was this which caused the obstruction. In two places the mucosa had become herniated through the muscular wall, forming pulsion diverticula (see Diagram). The wall of the subsidiary stomach was excised with the diverticula, leaving the common wall, from which the mucosa was completely removed. The remaining hypertrophied stomach wall was then found to be still partly obstructing the pyloric antrum, so a posterior gastro-enterostomy was performed.

The specimen consisted of five pieces of cyst wall, the largest measuring 3.5 by 1 cm. and 0.5 cm. thick. The walls consisted of thick muscle, lined by gastric mucosa. The fluid contained in the cysts was colourless and slightly opalescent, containing 6 g. of protein per 100 ml. Unfortunately tests for acid and pepsin were not performed.

Post-operative Progress.—Fluid requirements were given by scalp-vein infusion for the first four days, together with a transfusion of 100 ml. of blood. Feeds of half-strength Hartmann's solution were begun 48 hours after operation, expressed breast milk being substituted on the fourth day. His recovery was uneventful, although he was slow in gaining weight. His birth weight was not regained until the age of 3 months (4½ weeks after operation), but he then gained a further 13 oz. (370 g.) in the next 10 days.

A barium-meal examination on February 18, 1957, three months after operation, showed that the meal passed into the small intestine both via the pylorus and via the gastro-jejunostomy.

When seen on June 27, seven months after operation, he was very well, with no vomiting, his weight at the age of 9 months being 20 lb. 12 oz. (9.4 kg.).

I am grateful to Dr. F. S. W. Brimblecombe and Mr. A. C. Gairdner for permission to record this case, and to the nursing staff of the Royal Devon and Exeter Hospital for their care of the patient.

MARGARET E. R. STONEMAN, M.B., D.C.H.,
Paediatric Registrar, Royal Devon and Exeter Hospital.

Reviews

AORTOGRAPHY IN RENAL DISEASE

Aortography. Its Application in Urological and Some Other Conditions. By W. Barr Stirling, Ch.M., F.R.C.S.(Ed.), F.R.F.P.S.G. (Pp. 292+vii; illustrated. 50s.) Edinburgh and London: E. and S. Livingstone Ltd. 1957.

This monograph of about 290 pages relates the author's experiences of some 500 aortograms performed mainly for renal disease. Some vascular and other conditions are considered in a relatively short terminal section. The early chapters contain an account of the history, applied anatomy, and technique of the examination performed by the trans-lumbar route. There is an interesting chapter on pressure factors in the aorta. In a lucid account of the hazards and possible complications of the procedure, anuria following repeated injections, without extravasation of the contrast medium, has been omitted. The congenital variations of the renal tract and the importance of the blood supply are well illustrated and described and their surgical aspects are stressed. While the application of the investigation to polycystic disease is limited, not everyone would agree that the appearances are not specific. It is also refreshing to find that, in the author's opinion, the differentiation of simple cyst from cortical neoplasm is reliable, when the opposite view has recently been stated in the literature. I entirely endorse the author's opinion. The importance of the examination in the assessment of function and distribution of blood supply in hydronephrosis, renal calculus, and other conditions requiring reparative or conservative surgery is stressed and beautifully illustrated. In suspected renal hypertension, especially if the excretory pyelogram is normal, the examination may nevertheless reveal arterial insufficiency to the whole of part of one kidney. The book is well endowed with short case reports. As the author states in the preface, this monograph is not a textbook; nevertheless it is sufficiently comprehensive to form a basis for those interested in the examination and its possibilities.

C. G. WHITESIDE.

CHROMATOGRAPHY TECHNIQUES

Chromatographic Techniques: Clinical and Biochemical Applications. Edited by Ivor Smith, B.Sc., Ph.D., F.R.I.C. (Pp. 309+ix; illustrated. 45s.) London: William Heinemann Medical Books, Ltd. 1958.

Paper chromatography represents one of the most important advances in biochemical technique, and it has justly been given pride of place in the exhibition of British inventions at the Brussels World Fair. In medicine it has the particular advantage of using small quantities of material. It can be carried out without elaborate equipment and can be performed even by those who have not been highly trained. The widespread application of the technique has resulted in numerous papers distributed amongst a great variety of journals. It is often not possible to employ these methods without doing some additional research of one's own. Their reliability will have to be verified, and technical details more often than not have to be modified. A laboratory bench-book on chromatography techniques is, therefore, a most useful addition to the armamentarium of the medical laboratory worker. The title of the book is a misnomer. Chromatographic methods include adsorption chromatography in columns made of silica gel, alumina, and ion-exchange resins. These techniques are either not described or only mentioned in passing. The editor, Dr. Ivor Smith, is a postgraduate lecturer in chromatographic methods at the Technical College, Acton, London; he is also associated with the Courtauld Institute of Middlesex Hospital, London, and he is joined by J. P. Jepson, R. W. H. Edwards, A. H. Snaith, and H. G. Stevens from the Middlesex Hospital. Other contributors are J. V. Jackson from New Scotland Yard, T. Wood from Bovril Ltd., H. G. Horwell from

May and Baker Ltd., E. Kawerau from St. Mary's Hospital, and M. Birchenough from the Norwood Technical College, London. Amino-acids and amines, imidazoles, purines, sugars, the acids of the citric acid cycle, barbiturates, and steroids are amongst the compounds which are considered in detail. A most valuable contribution is that dealing with the indoles, including hydroxyindolylacetic acid and tryptamine. It is perhaps surprising, but presumably owing to the book's restriction to paper chromatography, that the useful work by Huisman and his colleagues on resin chromatography of haemoglobin variants is not mentioned. There are also chapters on chromatographic apparatus and techniques and two indexes—one general, dealing with more than 500 items, and the other of some 600 compounds named in the tables.

Considering the number of tables, diagrams, and illustrations, and the quality of the paper, the book is not expensive. It will undoubtedly become a standard laboratory bench book, and the authors and publishers are to be congratulated for having made a substantial contribution to laboratory practice.

H. LEHMANN.

ANATOMY AND HUMANISM

Anatomist at Large: An Autobiography and Selected Essays. By G. W. Corner. (Pp. 213. \$4.00.) New York: Basic Books. 1958.

Professor George Corner's eminence is well recognized in both anatomical and physiological circles. Distinction between the two departments, on the level on which he works, has indeed now almost vanished, but he is specially known for his discoveries on the sexual cycle of apes, which closely resembles that of the human subject. Thus much of his work is, or will be in the near future, of direct medical application. He was born at Baltimore in 1889, and has spent there most of his active life as student, investigator, and teacher. After a sound basic education he entered Johns Hopkins University, first "majoring" in classics and afterwards changing to science, especially biology, finally passing to a medical course. He was a pupil of the anatomists F. P. Mall and Florence Sabin, to whom he gives special acknowledgment. His clinical years were in the latter period of first blossoming of that great school, where William H. Welch, William S. Halsted, Howard A. Kelly, and Whitridge Williams were among his teachers. After several crowded years, which included a time spent in Germany and two seasons with the Grenfell Medical Mission in Labrador, where he met his accomplished wife, he spent a year in Great Britain with Starling, Bayliss, and Elliot Smith, finding time somehow to produce a distinguished piece of historical research, a line of work in which he always showed, and still shows, much interest. After acting as assistant to Herbert M. Evans in California he became professor of anatomy at Rochester, N.Y. There he remained until his return to his native city to occupy a research chair provided by the Carnegie Fund. In 1952 he was Eastman Visiting Professor at Oxford, when he was elected into the Royal Society. Soon after he became president of the American Philosophical Society. On retiring from his chair at Baltimore he undertook to write the history of the Rockefeller Foundation, on which work he is still engaged.

In addition to the autobiography, this volume includes a "type research" in substantially its original form. It is a happy idea to republish such a work, for, better than any other, it gives the reader a view of the investigator's real preoccupations. For this purpose he has selected his classical paper in which, with one of his students, he showed experimentally that the corpora lutea contain a specific hormone, a function of which is to induce pregestational proliferation of the endometrium in preparation for reception of embryos. He calls it "Search for a Hormone," and its results have elucidated the human menstrual cycle.

The lives of experimentalists are notoriously uneventful outside the laboratory, but Dr. Corner is exceptional in having had a richly varied career which has always been

coloured by humane purposefulness. In reading his essays one feels that the man is best reflected in his several addresses to students. They are the work of a scientist who, in his labours, has never lost sight of their possible application to medical practice. Here is none of the remoteness of the traditional professor. These student addresses especially maintain the dignity of a fine literary tradition. They reveal much of the personality of the author, who, in his turn, must surely have felt their delivery as a call and a charge. They show Professor Corner as a wise and experienced physician in the true Hippocratic mood, for "where the love of Man is, there also is love of the Art."

CHARLES SINGER.

PATHOLOGY IN THE U.S.A.

Pathology. Edited by W. A. D. Anderson, M.A., M.D., F.A.C.P., F.C.A.P. Third edition. (Pp. 1,402+xv; illustrated. £6.) London: Henry Kimpton. 1957.

The third edition of this standard textbook follows the general plan of its predecessors. Some parts have been completely rewritten, others revised, and a few shortened. The references have been brought up to date and the number of illustrations increased, and the binding appears to be more sturdy. As there are now 35 contributors, representing 17 of the 48 stars on the Union flag, "Anderson" can be regarded as fairly representative of the healthy state of the pathology in the United States. Great Britain and the London Hospital are represented by one author, Professor Dorothy S. Russell, who contributes an article on the pituitary gland. In the words of the editor, "a thorough coverage of the subject has been attempted within the limitations of a single volume." The reader will agree that this attempt has been singularly successful and the editor's purpose achieved by the exceptionally liberal use of small print. Few, if any, single-volume modern textbooks contain so much accurate and relevant pathological information. Dr. Anderson suggests that the large-print sections can be used by the junior student, and that he will increasingly need the "small print" as he progresses. There is no doubt that the book will continue to serve as a reliable reference book for advanced students, clinicians, and pathologists. While "morbid physiology" is by no means neglected, the background of this book is the accurate correlation of descriptive morbid anatomy and histology with clinical signs and symptoms. This interpretation of the word "pathology" in the United States is very probably related to the firmly established and highly commendable practice of holding clinico-pathological discussions on the majority of patients who die in their teaching hospitals. It is not improbable that we are tending to neglect this approach in Great Britain.

GEOFFREY HADFIELD.

WHITLA'S DICTIONARY OF TREATMENT

Whitla's Dictionary of Medical Treatment. Ninth edition. By R. S. Allison, V.R.D., M.D., F.R.C.P., D.P.M., and T. H. Crozier, M.D., B.Sc., F.R.C.P., and twenty-six contributors. (Pp. 854+xiii. 52s. 6d.) London: Baillière, Tindall and Cox. 1957.

This is the ninth edition of a book which first appeared in 1891, and the authorship has grown from a single man to 26 contributors. It is now the product of the Belfast school as a whole. While the authorship has increased, the territory covered has diminished; surgical topics have been omitted and the material is confined to medical therapeutics. The arrangement is alphabetical, and in general the items can be classified in four groups—the names of recognized diseases or syndromes, common presenting symptoms and signs, therapeutic procedures, and finally therapeutic principles underlying medical treatment. There are a detailed list of contents and a good index, so that the book is easy to read. The book is addressed to the senior student and practitioner, and does what it sets out to do extremely well. The instructions are modern and practical, and there are none of those relics of a bygone day which so often intrude

in texts of this age. Common diseases like coronary thrombosis are well handled. There is an excellent section on the painful lesions of the neck, arm, and shoulder, which are apologetically classified under the heading "brachial neuritis." Prescriptions are given in both the English and the metric system, but figures for the latter have been so literally translated that they would be extremely annoying to the chemist. For example, 15 minims becomes 0.9 ml. instead of 1 ml., and the equivalent of a dose of $\frac{1}{2}$ oz. is given as 14.2 ml. instead of 15 ml.

L. J. WITTS.

INTRACTABLE HEADACHE

Management of the Patient with Headache. By Perry S. MacNeal, M.D., F.A.C.P., Bernard J. Alpers, M.D., Sc.D.(Med.), F.A.C.P., and William R. O'Brien, M.D., F.A.P.A. (Pp. 145. 26s.) London: Henry Kimpton. 1957.

Intractable headache or frequently occurring headache is not an uncommon problem in most types of medical practice. To those concerned with questions of differential diagnosis and of treatment this little book may be of some interest, and even perhaps of limited value. The attainment is uneven, as might be expected when such a wide subject is tackled by multiple authorship. The sections dealing with psychopathology and with the personality traits of the migrainous sufferer are frankly unconvincing, naive, and unacceptable. One feels at times tempted to protest, like Oscar Wilde: "You must not find symbols in everything you see. It makes life impossible." With much of what the authors have to say about the medicinal treatment of migraine—both in and between attacks—no one can quarrel, and many medical men will indeed appreciate the clear exposition of the present position of drug therapy. Some of the *obiter dicta* are shrewd: "... History is far and away the most important part of the study of a patient with headache. The physical examination helps some [sic] and laboratory studies least of all. The skull x-ray, ordered so frequently, is almost uniformly a waste of time and money. We have seldom seen a simple x-ray study of the skull reveal anything of importance in the study of the patient with the chief complaint of headache." None the less the wise physician will continue to utilize routine radiology, not only of the skull but also of the chest, in the investigation of his patients with intractable headache.

MACDONALD CRITCHLEY.

THE ADRENALS IN DIABETES

Cortico-surrénale et Diabète Humain: Relations entre le Diabète Stéroïdien et le Diabète Ordinaire. By P. Bastenier with eight contributors. (Pp. 506; illustrated. 4,000 frs.) Paris: Masson et Cie. 1956.

This is a comprehensive review of the role of the adrenals in human diabetes. Virtually the whole range of human diabetes is discussed, from the rarer syndromes of the Cushing and Achard-Thiers type to the more commonly occurring disease encountered in everyday clinical practice. The earlier part of the book has chapters devoted to the basic physiology and biochemistry of diabetes, and these are exhaustively dealt with. Succeeding chapters are concerned with methods used in investigating the metabolism of glucose and steroids and the fate of steroids in man. After chapters dealing separately with acromegaly and Cushing's syndrome, space is devoted to the classification of human diabetes. Some interesting analogies are drawn between the obese type of human diabetes (the Continental *diabète gras*) and Cushing's syndrome on both clinical and experimental grounds. The possible part played by the adrenal cortex in the genesis of diabetic vascular complications is discussed at length, as is both the surgical and medical therapy used in this condition. The volume is well produced, with some good diagrams and clear photographs. Even though at times it is provocative, this book, with its wealth of references, will be very valuable to clinicians and research workers alike in this highly controversial field.

K. W. TAYLOR.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 27 1958

IMMUNOLOGICAL SPECULATIONS

The skin is a well-recognized mirror of systemic diseases. Initial observations on lupus erythematosus and sarcoidosis stemmed from dermatologists; but, later, specialists in other disciplines were to contribute to the evolution of knowledge. The first step forward was the recognition that they were not primarily dermatological curiosities, but instead disorders frequently affecting tissue systems throughout the body. Once this was established, the terms disseminated, systemic, and generalized were bestowed to include manifestations remote from the original skin disease. Thus far, study of the diseases had been a meeting-point for the dermatologist, general physician, and pathologist. But it became evident that the diagnosis could be made with some confidence in the absence of skin lesions. Although the field of interest of the physician had now eclipsed that of the dermatologist, he still relied on the morbid anatomist for corroborative histological evidence of the "onion-skin" and "wire loop" vascular lesions found respectively in the spleen and renal glomeruli in lupus erythematosus.

Emphasis is once again shifting, this time from the histological to a more dynamic immunological approach to these and other disorders. Acute lupus erythematosus gives clinical, histological, and haematological evidence suggesting a hypersensitivity mechanism. E. G. L. Bywaters¹ and W. Dameshek² have suggested that this may be of the auto-immunization variety. The severe constitutional upset with fever, polyarthralgia, serositis, nodules, lymphadenopathy and also the peculiar vasculitis observed histologically have for long suggested an allergic response, similar in some respects to serum sickness and drug allergy. To this picture may be added a set of associated haematological disturbances—haemolytic anaemia, leucopenia, thrombocytopenia, and coagulation defects. That these are linked with a positive Coombs test, the L.E. cell factor, platelet agglutinins, false-positive serological tests for syphilis, isoagglutinins after blood transfusion, and raised serum gammaglobulin levels all support the thesis that an immunological disturbance is responsible.

Dameshek considers that these clinical, histological, and haematological features of systemic lupus erythematosus portray the end-result of a series of reactions directed against the endothelium of blood vessels and against red corpuscles, white cells, platelets, and blood-coagulation factors. In our present degree of ignorance of these reactions the speculation is a reasonable one and it is certainly fashionable to confer the term "auto-immune" on a set of reactions which apparently arise within the host's own body and attack various constituents of his own tissues. It remains to be seen whether a responsible antigenic substance is uncovered. Hydrallazine is known to produce a syndrome resembling lupus erythematosus, and the L.E. cell has also been detected in the serum of patients with hypersensitivity reactions to penicillin. It is possible that these or similar chemicals may so alter the cell surface as to render it antigenic.

Another factor which might be usefully entertained in discussing the pathogenesis of disseminated lupus erythematosus is its conspicuous predilection for women of the child-bearing years of life. In fact, Dameshek² states that he has observed it only in three males, two of whom had received hydrallazine and the third penicillin, all for prolonged periods. He suggests that the active endometrium is an ideal milieu for the production of antigenic substances from altered blood cells and blood vessels, associated as it is with large pools of stagnant blood. He also suggests that the periodic character of the catamenia might play a significant part, corresponding to "booster" injections in an immunization procedure or sensitization process. Although this stimulating concept cannot at present be verified, it does not preclude us from attempting to analyse our data of other ill-defined conditions in a similar light. Sarcoidosis has been mentioned as a dermatological curiosity which was extended to become a disorder of general medical interest. Radiology and tissue biopsy provided means of establishing the diagnosis in the absence of skin lesions. The occurrence of fever, polyarthralgia, erythema nodosum, and acute iritis at its onset, the depression of delayed-type (tuberculin-type) skin-test reactions, the abnormal serum globulins, and the Kveim test phenomenon could all be construed as evidence of hypersensitivity or of reticulo-endothelial imbalance. G. Teilmann³ brackets both disseminated lupus erythematosus and sarcoidosis as examples of allergic hyperglobulinosis. Moreover, erythema nodosum due to sarcoidosis also predominantly affects women during the reproductive years of life. For the present these may appear to be a series of unlinked observations, but an immunological approach holds the exciting promise of a connecting thread.

SYMPTOMLESS JAUNDICE

If the serum of apparently normal blood donors is analysed for bilirubin content, a proportion will be found above the normal upper limit of 1 mg. per 100 ml. A few of these subjects will be suffering from congenital spherocytosis (acholuric jaundice), which is readily diagnosed by examination of the peripheral blood film, reticulocyte count, and erythrocyte fragility tests. An even smaller number will be shown to suffer from a well-compensated Laennec's cirrhosis, and other stigmata of liver disease such as vascular spiders on the skin, hepatomegaly, or splenomegaly will often be found. Sero-flocculation tests such as thymol turbidity may be positive, and injected bromsulphalein is usually retained abnormally. There remains the group of congenital hyperbilirubinaemias which are now attracting much general interest. The most frequent is Gilbert's disease,^{1,2} which is inherited as a dominant characteristic. Mild jaundice with tiredness and languor are noted intermittently. There are no other abnormal physical signs. Histological examination of liver-biopsy material shows normal appearances.³ Bile pigment is not present in the urine. J. F. Crigler and V. A. Najjar⁴ have described what is probably a more severe form of Gilbert's disease in which jaundice is deeper. The circulating serum bilirubin is unconjugated with glucuronide ("indirect" type) and has an affinity for nervous tissue, so that the features of kernicterus are present. A biochemical defect in the conjugation of bilirubin with glucuronic acid in the liver has been demonstrated in deeply jaundiced patients with the Crigler-Najjar type.⁵ The specific defect seems to be in glucuronyl transferase, an enzyme which is present in hepatic microsomes and which transfers glucuronic acid from uridine diphosphate glucuronic acid to various receptors, including bilirubin.⁶ The liver in Gunn's strain of congenitally jaundiced Wistar rats has been shown to have a similar defect.⁷ Diminution of conjugation of other substances with glucuronic acid has also been shown: these include menthol, salicylates, and metabolites of cortisone.^{8,9} The patients and the rats were much more icteric than the usual sufferer from Gilbert's disease. Difficulty has arisen in confirming these results in the mildly icteric, and more recently it has been shown that patients

with Gilbert's disease conjugate administered salicylamide¹⁰ and also menthol¹¹ with glucuronic acid normally. Nevertheless the demonstration of a specific hepatic enzymatic defect in the severe forms of the disease represents an important advance, and results of the wider application of these methods to other forms of jaundice will be awaited with interest.

The third, rarer, form of congenital hyperbilirubinaemia was first described in 1954 by I. N. Dubin and F. B. Johnson¹² as "chronic idiopathic jaundice with unidentified pigment in liver cells" and by H. Sprinz and R. S. Nelson¹³ as "persistent non-haemolytic hyperbilirubinaemia associated with lipochrome-like pigment in liver cells." Dubin has recently reviewed 50 cases of the disease.¹⁴ The disorder differs from the Gilbert type in that the circulating bilirubin is conjugated with glucuronide ("direct" type) and is water-soluble and so appears in the urine. The essential defect is not in the conjugation of bilirubin but in its excretion into the bile. The main point of distinction is in the liver, which, macroscopically, is greenish-black. Dubin¹⁴ has even suggested that the disease might be termed "macro-hepatic icterus" or "black-liver jaundice." The pigment is found in liver cells and belongs to the family of lipofuscins, the so-called "wear and tear" pigments. It has not been chemically identified.

Both Gilbert's and the Dubin-Johnson type of congenital hyperbilirubinaemia carry an excellent prognosis. Their distinction one from the other remains of theoretical rather than clinical interest. The differentiation from the more serious types of chronic intermittent jaundice is, however, of great practical importance and merits the fullest biochemical and haematological investigation, perhaps necessitating aspiration liver biopsy.

TISSUE BUILDING AND PROTEIN ANABOLIZERS

The metabolic pool is a useful concept, allowing us to make a mental image of the circulating fluid to which nutrients, hormones, vitamins, and degradation products each add their quota and from which at any hour of the day or night, in each deviation from health and in all the seven ages of man, the body seeks to supply its varying demands. Even if we narrow our field of vision to the best understood of the products of metabolism, glucose,¹ we soon find that ignorance outweighs understanding, and if we press our inquiry as far as the uptake and utilization of glucose by the cell mystery enwraps us. As to the metabolism of proteins, the situation is even less accurately defined: we know that growth requires an increased amount of protein, and we can measure

this by the amount of nitrogen retained in the body. We know, too, that in certain catabolic states—accident, operation, inflammation, and neoplasm—an increased amount of protein is broken down and utilized in unusual ways, by gluconeogenesis, for example, and we can in these conditions measure the increased loss of nitrogen from the body. When the body enters the stage of protein repair, then nitrogen is retained in excess until complete restitution occurs. Hormonal agencies such as the protein anabolizers, growth hormone, and the androgens control the build-up of protein. Cortisol is recognized as the main protein katabolizer, and in his Burns lecture D. Hubble² attempted the construction of a hormonal formula for the metabolism of protein. Although the balance may be tipped in either direction in disease states, yet we have to assume that the body each hour in each day maintains its predestined balance between protein building and protein breakdown, and no one would wish lightly to interfere with it.

In many disease states, however, there is great protein loss, and the need for increased protein anabolism is often seen. In recovery from acute illness,³ from operations,⁴ from accidents,⁵ and from severe burns⁶ it is rational therapy to encourage as rapid a protein build-up as can be obtained. Since the growth hormone is not available for protein anabolism in man, testosterone in some form can be employed for this purpose. This has the disadvantage, when used in women and children, of a strongly virilizing action, and effective alternative preparations with a much weaker androgenic action than testosterone have been long awaited. The synthesis of the 19-nortestosterone group ("nilevar" and "durabolin") is a step towards meeting this need, for the protein-anabolizing effect of these compounds is equal to that of testosterone and the virilizing effect is said to be slight. It has, however, been stated recently that these new compounds definitely cause virilism,^{7,8} though they are markedly less androgenic than testosterone. When, therefore, they are used for long periods in women and children such undesirable consequences must be carefully looked for. Methyl testosterone has for many years been available for use as a stimulus to protein anabolism in men, and it is salutary to remember, while welcoming the new and

expensive remedies, how little it has in fact been used in supportive therapy.

Fuller Albright⁹ first described the anti-anabolic action of the glucocorticoids on protein metabolism—an action which produces some of the most characteristic of the symptoms of Cushing's syndrome—and suggested the use of testosterone in therapy. There are to-day much more effective treatments for this disease, but if for any reason surgery is contra-indicated and x-ray therapy fails then the new protein anabolizers should be used. With long-continued therapy by cortisol or any of its associated compounds in moderate or high dosage it is rational—particularly in children to assist growth and in post-menopausal women to prevent osteoporosis—to use the 19-nor-testosterone derivatives. There are other indications for the use of the protein-anabolizers. Since we have no growth hormone for therapeutic use, these new remedies should be valuable in hypopituitary dwarfism and might also be tested in other forms of dwarfism.¹⁰ Stimulation of growth by testosterone has to be undertaken with great care because of its androgenic effect, but this hormone has been used with some success in the treatment of carcinoma of the breast with dissemination to bones. This good effect has been attributed to a consequent change in the hormonal environment of the cancer, possibly resulting in some depression of oestrogen action by testosterone. If this is so, no good result would be expected from the use of 19-nor-testosterone in this disease, and the manufacturers of Nilevar, while recommending its use in carcinomatosis as a stimulant to protein metabolism, expressly disclaim for it any specific action on bone metastases. In another common disorder, osteoporosis in women, oestrogens have been shown to be effective in treatment¹¹; methyl testosterone has also been used as an additional therapy in small doses and in interrupted courses. If, for any reason, it is necessary to supplement the action of oestrogens, then 19-nor-testosterone should be used.

The therapeutic indications for these new protein anabolizers are, then, in stimulation of growth in the dwarfed of both sexes, in aiding the recovery of women and children from any illness in which there has been severe protein loss, whether acute or chronic, and in protecting the skeleton against the harmful action of the glucocorticoids. The cost of one week's treatment by Nilevar may be from £3 to £5 (more than seven times as expensive as the equivalent treatment by methyl testosterone), and an expenditure of this sort, especially if long continued, may be thought justifiable only when an express need for the treatment is apparent.

THE NATURE OF PENICILLIN SENSITIVITY

Reactions to penicillin may be of two kinds. In one, skin manifestations predominate, whether the reaction is due to contact or to parenteral injection: they are of urticarial type and, if extensive, are accompanied by fever. The second and more dangerous kind of reaction is immediate shock, which if not immediately treated may be fatal within a few minutes. The fact that sensitivity can manifest itself in two quite different ways requires explanation, and emphasizes the importance of understanding the basis of these states. A test for sensitivity may sometimes be desirable, and various methods have been used. S. Swift¹ suggests a scratch test, followed by intradermal injection if the former is negative. He describes two kinds of reaction, an immediate one denoting the anaphylactic type of sensitivity, and a delayed reaction seen in patients with sensitivity of the urticarial or "serum sickness" type. Not every one has had such consistent results, and several authors complain that patients who have exhibited sensitivity fail to react to such tests. O. Idsøe and P.-N. Wang,² reporting on reactions to penicillin in Taiwan (Formosa), give the results of skin tests for sensitivity performed on 48 of 106 patients in whom reactions occurred to the subsequent injection: these tests had been negative in all patients developing severe or even fatal shock, and positive only in a proportion of those with milder shock or urticaria. On the other hand, there is the opposite difficulty of an unduly violent reaction to a test. P. S. Mayer and his colleagues³ caused shock with a test dose of only 10 units.

According to Swift, sensitivity is passively transferable, which would signify the formation of an antibody, and, since penicillin while in the blood stream is to some extent bound to plasma albumin, it has been supposed to function as a haptene. If indeed antibody formation is the basis of sensitivity, the antibody should be demonstrable. Two recent papers make the claim that this has been achieved. R. J. Muelling and colleagues⁴ have carried out an investigation on 100 patients who had exhibited sensitivity either to penicillin or to one of several other antibiotics. They tested for antibodies in the serum of these patients by the method of diffusion in a gel, the serum being incorporated in agar at the bottom of a tube and covered with a layer of agar separating it from a solution of the antibiotic: lines of precipitation appearing in the intervening layer indicate the presence of antibody. Of 71 sera from patients suspected of penicillin sensitivity, 34 gave positive results. A few positive results were also obtained with several other antibiotics, including even tetracyclines, to which sensitivity is reputed to be very rare. There are some strange features in these findings, notably the long delay which seems sometimes to have occurred before a precipitate appeared (it is said to be advisable to continue the test for 21 days) and the occurrence of double bands when in fact the antigen is a single one.

Nevertheless other workers will doubtless wish to explore this method of detecting antibody.

The other observation, reported by Allyn B. Ley and her colleagues,⁵ of New York, is more positive and immediately significant. It arose from a chance finding. The serum of a patient requiring transfusion was found to agglutinate every suspension of red cells to which it was added. These had been preserved with penicillin. Fresh cells from the same individuals were unaffected, and, on the other hand, cells of any blood group to which penicillin had been added became agglutinable by this serum. The examination of about 2,000 further sera revealed 25 more possessing this property. All the people from whom they were obtained had at some time been treated with penicillin, but "only a minority" had exhibited penicillin sensitivity. To sensitize cells to the antibody in these sera they had to be suspended in rather high concentrations of penicillin: a 25% cell suspension required 3,000 units per ml. for 24 hours or higher concentrations for a shorter period. Admixture with concentrations of the same order deprived serum of the capacity to agglutinate sensitized cells, presumably owing to binding of the antibody. It was also found possible to elute the antibody from agglutinated cell suspensions by heating to 54° C. The clinical significance of this antibody remains to be determined, but its discovery provides another test which should certainly be applied in cases of clinical sensitivity, and may well stimulate a search for other methods of detecting the changes on which sensitivity depends.

PEPTIC ULCER AND SECRETOR STATUS

That the occurrence of peptic ulcer is associated with blood group O is now well established. Results obtained from over 12,000 patients with peptic ulcer indicate that the risk of duodenal ulcer is about 38% more and the risk of gastric ulcer about 19% more for subjects with blood group O than for other subjects.¹ While the increased risk is, thus, not great, it has been observed in eight countries, and it is difficult to believe that the association could be an artifact due to the existence of strains within each national population who were both high in group O and particularly susceptible to peptic ulceration. In fact, the blood group antigens (group substances A, B, and H in persons of blood groups A, B, and O respectively) are mucopolysaccharides and form an important proportion of the mucins normally secreted in the gastro-intestinal tract, so that it would be reasonable to suppose that the association between blood group and disease was a direct result of a difference in the local physiological effects of the different substances. Not all persons, however, secrete the ABH substances, and if this hypothesis were true it might be supposed that non-secretors would be more susceptible to the disease than secretors. Moreover, in these circumstances, it would be expected that a

difference in the susceptibility of persons of different groups would be found only among those whose gastro-intestinal mucus contained some of the relevant group substance. These possibilities were first investigated by Clarke and his co-workers at Liverpool,^{2,3} and, as was expected, the proportion of non-secretors among duodenal ulcer patients was found to be greater than among a control group of healthy subjects (35.0% against 24.2%). But, contrary to expectation, the proportion of group O subjects was found to be just as great among the non-secretors with ulcer as among the secretors. This result has now been confirmed by J. Wallace and colleagues.⁴ Among 181 subjects with duodenal ulcer belonging to blood groups A, B, and AB the proportion of non-secretors was 37.0%, against 23.5% among a control group of patients with non-gastro-intestinal disease, whereas among group O subjects the proportions were 39.5% and 28.7%. It seems, therefore, that the greater susceptibility of group O subjects is independent of the presence of the H antigen in the mucous secretions, and the association between blood group and disease can hardly be regarded as due to a direct local effect. Further evidence that this is not the explanation is provided by the data on the distribution of blood groups within ulcer families. C. A. Clarke and R. B. McConnell's most recent data were reported at the symposium on medical research, Wisconsin University, on April 7-10 last. They have now studied nearly 400 duodenal ulcer sibships, and, though these show some slight predominance of group O subjects and of non-secretors among the ulcer patients in comparison with their healthy sibs, the excesses are very slight. These workers have therefore felt obliged to suggest that a maternal factor might be involved, and that mothers who are group O may be more likely to produce children who will develop a duodenal ulcer than mothers belonging to any one of the other groups.

Obscure though the explanation now is, the recent data on secretor status provide the most encouraging clue to the aetiology of peptic ulcer that has been obtained for many years. Taken in conjunction with the data on distribution of blood groups, they point to a factor of considerable importance. For it can be shown that the risk of developing the disease among non-secretors who belong to group O is nearly 2.5 times as great as among men whose mucous secretions contain the A or B antigens, and, according to Wallace and his co-workers, the relative risk of developing an ulcer severe enough to warrant operation may be even higher.

THE JOHN CURTIN SCHOOL

In March the permanent building of the John Curtin School of Medical Research was officially opened. The school, situated in Canberra, is the fourth of the Australian National University's research schools, the others being those for the physical sciences, the social sciences, and for Pacific studies.¹ Founded in 1946, the National University is Australia's answer to the old

complaint that so many of her ablest scientists are lost to universities and research centres abroad, a complaint that was perhaps particularly justified in the case of medical scientists. Other Australian scientists had the many fine laboratories of the Commonwealth Scientific and Industrial Research Organization, whereas the only native medical research centre with an assured international reputation was in those days the relatively small Walter and Eliza Hall Institute in Melbourne. The opportunities for the new school, under its dean, Professor A. H. Ennor, are thus great.

Appropriately it was Sir Howard Florey who performed the opening ceremony, in the presence of a distinguished company which included the Prime Minister of Australia, for it was Sir Howard's recommendations to the Government of the day that supplied the critical stimulus for the school's birth. In 1944, in a report to the Commonwealth Government, he recommended the setting up on Australian soil of a national institute for advanced medical sciences, and the John Curtin School is the direct result of this suggestion. Later, when his proposal had become accepted policy, Sir Howard Florey guided the school's development. In 1948, when the first professor was appointed, it had no laboratories of its own and its various departments therefore began by being housed in accommodation generously lent by other institutions—the department of biochemistry at the Commonwealth Serum Laboratories, Melbourne; the department of medical chemistry at the Wellcome Research Institution in London; the department of microbiology at the Walter and Eliza Hall Institute; the department of experimental pathology in Sir Howard Florey's laboratories in Oxford; and the department of physiology at Otago University. By 1951 temporary laboratories were ready in Canberra, and the departments were set up there until their move last year to their permanent home. At present the total research staff is about 40 and there are some 20 Ph.D. students, but the school is still in the process of growth, both in the sense that over the next few years several new departments are projected and in the sense that each department has yet to reach its own maturity. The new building provides first-rate facilities for research in a wide range of the medical sciences, and already the John Curtin School has earned itself a name known throughout the world.

BLACK PATCH DELIRIUM

Mental illness occasionally follows a surgical operation, just as it may follow childbirth, often after a short interval, and the symptoms may be those of mania, depression, or a schizophrenic state.¹ More rarely the mental symptoms are those of a confusional state, and may come on immediately, particularly in the elderly and arteriosclerotic. Since operations for cataract are performed predominantly on elderly patients, it is not surprising that "cataract delirium" or "black patch

¹ Stengel, E., Zeitlyn, B. B., and Rayner, E. H., *J. ment. Sci.*, 1958, 104, 389.
² Solomon, P., Leiderman, P. M., Mendelson, J., and Wexler, D., *Amer. J. Psychiat.*, 1957, 114, 357.
³ Weisman, A. D., and Hackett, T. P., *New Engl. J. Med.*, 1958, 258, 1284.

delirium" should be well known to ophthalmologists. It appears to be due to the fact that both eyes are bandaged after operation. The temporary total blindness leads to disorientation, with restlessness, suspicion, and anxiety as its commonest signs. This is reminiscent of the temporary mental disorders that have been induced in volunteers by keeping them in darkened, sound-proofed rooms, their limbs completely covered, so that sensory stimulation was minimal.² But in the patients submitted to surgical treatment of the eyes the confusional state is more easily produced, perhaps because of a degree of concomitant deafness or dementia. A. D. Weisman and T. P. Hackett³ have reported cases in which the risk of a confusional state was averted by brief psychotherapy before operation. The psychiatrist endeavoured with each patient to establish himself as a recognizable individual in a recognized place, and used not only talk, but the scent of flowers, touch, and taste, to get into a warm relationship with the patient. He reappeared after the operation to remind the patient of orientation in space and time, and to reassure him on the successful outcome of treatment.

CONTRACTUAL VALIDITY OF SPENS

The Secretary of State for Scotland has refused to join with the B.M.A. in testing the contractual validity of Spens under Scottish law. The legal procedure in which the Minister had been asked to join with the B.M.A. was that of presenting a special case to the Court of Session. A special case is a device, peculiar to Scottish law, which enables parties amicably to agree to put their differences of opinion to the Court for an objective decision. The procedure was one which appeared particularly apt for settling, so far as doctors in Scotland were concerned, in an atmosphere of good will far removed from that of the usual type of contentious litigation, the divergence of views between the profession and the Government on the proper interpretation of the Spens Committee's recommendations. And the Chairman of Council's announcement¹ to the Representative Meeting at Birmingham that the Minister had been asked to participate was received with enthusiasm. The Secretary of State's refusal, as reported in this week's *Supplement*, can be only interpreted as another example of the Government's distaste for any calm and objective discussion of the Spens Reports.

IN NEED OF HELP

The generosity of individual doctors has enabled the Royal Medical Benevolent Fund to grow over the years, but, as its latest report says, "the necessity has also but, as its latest report says, 'the necessity has also grown appallingly.'" Expenditure last year is witness to this: it was £51,194, leaving a surplus of only £132. Many cases of desperate need among doctors and their families are beyond the reach of State or other aid, and here the R.M.B.F. is indispensable to relieve their distress. A new venture is the purchase of a house in Putney for conversion to five self-contained flats to accommodate indigent doctors.

¹ *Brit. med. J., Supplement*, 1958, 2, 80.

All doctors are urged to contribute what they can to help their unfortunate colleagues through this charity. By signing a seven-year covenant the Fund's income can be substantially increased without further cost to the subscriber, and there are also other ways in which the Fund and its ally, the Ladies' Guild, can be helped; full details of them can be obtained from the Secretary of the Fund at 1, Balliol House, Manor Fields, Putney, London, S.W.15.

ANNUAL CLINICAL MEETING AT SOUTHAMPTON

In the *Supplement* this week we print the programme of the Clinical Meeting which is being held in Southampton from December 4 to 7. This will be the first Annual Clinical Meeting to be held following the approval by Council of the Organization Committee's proposal¹ that a second scientific meeting should be held each year in addition to the Annual Meeting. The variety of the subjects chosen for the panel discussions and general sessions can be seen from the programme, and anyone who attends all the meetings and some of the clinical demonstrations will have had a concentrated refresher course presented in the most agreeable way possible. Not only will there be easy ways to learning through colour television and film shows, but during the afternoon of Friday, December 5, the American Medical Association's winter meeting in Minneapolis will be linked by telephone with the B.M.A.'s meeting in Southampton for the purpose of a transatlantic clinical conference: this novel event will no doubt have its entertaining as well as instructional aspects. Perhaps before Southampton welcomes an Annual Clinical Meeting for the second time transatlantic conferences may be linked by vision as well as sound. The local organizers of the meeting under the chairmanship of Dr. R. S. Russell-Smith have arranged what should prove to be an excellent clinical meeting, and on the social side too there will be much to enjoy in a short time. In every way it seems that Southampton is setting an admirable example to other towns which may be the venue of future Annual Clinical Meetings.

Members of the British and Canadian Medical Associations will receive with regret the news in this week's *Supplement* that their President-Elect, the Duke of Edinburgh, will be unable to be present at the Joint Annual Meeting of the two Associations in Edinburgh in July, 1959, since he will be with the Queen in Canada for the whole of that month.

Sir Arthur Porritt has agreed to act as chairman of the committee to review the medical services which is being set up under the joint sponsorship of the Royal Colleges, the Scottish Royal Medical Corporations, the British Medical Association, the College of General Practitioners, and the Society of Medical Officers of Health.

A SURVEY OF 100 CONSECUTIVE CHILDREN AWAITING ADMISSION TO A MENTAL DEFICIENCY HOSPITAL

BY

M. W. G. BRANDON, B.A.Dip.Ed.

AND

M. F. CRAIB, A.M.I.A.

Fountain Hospital, London

Owing to the acute shortage of beds in mental deficiency hospitals, the problems connected with long waiting-lists are becoming more serious. Parents may have to wait several years before they are offered a place for their child. The Fountain Hospital, of 600 beds, usually admits children under 5 years; in theory they should be transferred in early adolescence to other mental deficiency hospitals, but, owing to the limited provision for adult low-grade defectives, the number of transfers is small. A few children improve enough to be accepted for educationally subnormal schools or schools for the handicapped, etc. (Kirman, 1958; Craib and Woodward, 1958). Vacancies also occur when children go home on licence, die, or move to other branches of this hospital. The area covered by this survey included south-east London, south-west London, and Surrey, thus presenting the problems of both town and country.

The aim of the survey was to assess the social and psychological problems associated with young defectives awaiting admission. Statutory supervision is carried out by the local authority while the defective child remains at home, and the present practice is generally for the home to be visited by the hospital social worker when a vacancy is being considered. Out-patient appointments are made when the parents particularly request this.

Method

The Fountain Hospital is situated within the London area, and in 1948 the administration was taken over by the South-West Metropolitan Regional Hospital Board. Owing to the need for these children to be visited regularly and the demand for beds for young defective children, arrangements were made to admit children from the London administrative areas outside the jurisdiction of the regional board. Vacancies are allocated between the areas, and additional vacancies are credited to the individual regional hospital boards which arrange transfers to adult hospitals for patients becoming too old to remain in this hospital. Of those still awaiting a vacancy there are over three times as many from one area as from the others. In our visiting, therefore, it was not surprising that many of the most urgent cases were found in this one area.

The survey deals with 100 consecutive names on the hospital waiting-list. The period covered was from September, 1955, to May, 1957. A combined visit was paid to the home by the social worker and psychologist, after making a written appointment. In the present inquiry this visit was made much earlier than usual. The ordinary hospital pre-admission form was completed by the social worker with the mother. This form is designed to obtain medico-social information about the child's early history together with his physical development, any previous hospital treatment, and the family circumstances. The precipitating factors which led the parents to ask for admission were noted and the psychologist tested the child and discussed his early development and present abilities with the mother.

Material

At the time of writing 50 of the 100 children no longer required a vacancy at this hospital: 12 had died, 21 had

been admitted to other M.D. hospitals, 8 were no longer considered mentally deficient, 5 were able to stay at home, and in 4 cases the parents had moved from the catchment area. Of the remaining 50, 39 were still waiting admission and 11 had been admitted or offered a vacancy.

In 64 cases the reasons the child needed hospital care were discussed with the parent or guardian. These 64 cases included the 50 still on the waiting-list or admitted, plus 14 who later had their names withdrawn for reasons such as death or admission to other hospitals. In each case the main precipitating factor was assessed as well as any additional factors; these are given in Table I. Some of these factors need further amplification.

Factors Precipitating Request for Admission

	Main	Additional
(1) Physical care of the defective had become too much for the mother	18	7
(2) Parents wanted the defective's name retained on the waiting-list for the future	13	0
(3) Defective in the care of the children's officer	7	0
(4) Parents concern over the adverse effect on their other children	6	13
(5) Hospital care considered necessary for defective or the child removed at birth	5	10
(6) Parents abroad	4	0
(7) Family illness or birth of a further child	3	6
(8) Defective's behaviour was disturbed or destructive	3	1
(9) Marital disharmony	3	1
(10) Housing difficulties	1	8
(11) Parents considered that the defective needed hospital training	1	0

(1) In most cases it appears that it is the physical strain of looking after the child that precipitates a request for admission. Some of these children are heavy and helpless, and the strain on the mother becomes too much. When temporary care can be arranged (up to a maximum of eight weeks), this sometimes enables the mother to keep the child at home. For many mothers in this group there is the added emotional strain of having a severely handicapped child; the extent of this could not be assessed in a single interview.

(2) A number of parents realized that they would not always be able to care for the defective at home, and some felt the security of having the child's name retained on the waiting-list in case an emergency arose.

(3) Seven of the children have no home, are illegitimate, or have been abandoned. Whilst awaiting admission these children are placed in a nursery or foster home by a children's officer.

(4) For many normal children a defective sibling is an embarrassment and a tie, and the mothers cannot give them as much time and attention as they need. Although the main precipitating factor is rarely the welfare of other children, nearly a third of the parents were considering their needs when asking for admission.

(5) Some of the most tragic families are those where the parents, having been told soon after birth that the child is mentally deficient, are then strongly advised to apply for immediate hospital care. In three cases the child was separated from the parents when 2 weeks old and was then transferred to a private nursery while waiting for a hospital vacancy. The hydrocephalic child and the mongol child are particularly prone to such circumstances. The hydrocephalic child may need more medical and nursing care than can be given at home, but the baby mongol presents no nursing problem in normal circumstances. In the families in this group where the mongol baby has been separated at 2 weeks, serious emotional difficulties in the parents have arisen. Some parents who were unable to afford a private nursery have later expressed their thankfulness at having given their child a period of home care during his early life. Only a small proportion of parents felt it was "right" for their child to be away from them. From the point of view of the child's emotional needs, a hospital for mental defectives is no adequate substitute for the individual care given by a mother.

The remaining precipitating factors are self-explanatory; it will be noted that housing difficulties hold a relatively low position, although they appear to be an important subsidiary factor.

Psychological Tests

This survey was planned so that the children could be tested by a psychologist before they were admitted to a mental deficiency hospital, enabling them to be seen in their homes with their mother present. This was found to be helpful, as the mother was often able to describe the young child's achievements very accurately. However, directly speech was used to any considerable degree in testing, mothers found it difficult not to encourage the child, rephrase the question, or give the answers. From the mother's point of view, she could discuss the child's abilities on a developmental type of test with interest and very little guilt, but directly the child was asked to do specific items or to name objects, several mothers made remarks such as, "I haven't been able to teach him that yet," or, "Should I have done that with him?" or a more defensive and aggressive reaction was given such as, "Well, he couldn't do that because he's never played with things like that before." This last was said referring to test material which is usually new to a child.

Some of the mothers of mongols and gross idiots were very pleased to have their child tested; mothers of these children with rather obvious defects sometimes felt that in children with rather obvious defects sometimes felt that insufficient time had been spent examining the child's abilities. Before this survey was carried out it was not appreciated how helpful a test can be to a mother in recognizing for herself the approximate level her child has reached and in realizing that, although his development is slow, it is progressing along the same lines as that of other children.

In spite of the advantages of testing in the home, it seems preferable that the parents should visit the hospital, bringing the child as an out-patient, and that testing should be carried out by a psychologist then, leaving the social worker to visit the home alone. With a small group of children who show disturbed behaviour, however, it might be very valuable to see them in their own homes, as their behaviour sometimes appears to change markedly on admission.

The testing was carried out to find the I.Q. scatter in 100 children awaiting admission and to investigate any who might later be considered educable. But, for the reasons already given, testing of the whole 100 was found to be impossible, so that the children described are the 50 remaining on the waiting-list or already admitted.

The children were tested with the Griffiths mental development scale and/or the Vineland social maturity scale, except for one mongol of 7 who was given a Terman - Merrill revision of the Stanford-Binet test, Form L. Where two tests were given the scores were averaged. This is of course not standard practice, but was suitable for the purpose of this survey. The results are given in the Chart.

The average I.Q. of this group was 25, with a range from 2 to 84. All the children with I.Q.s over 50 were mongols. The average age of all the children on June 30, 1957, was 2.9, with a range from 3 months to 7 years. It was found that these children divided naturally into four groups—mongols, other imbeciles, idiots, and a group of children who showed severe behaviour disturb-

ances and were consequently very difficult to assess accurately. In the whole group there were over three times as many boys as girls, the numbers being 38 boys and 12 girls. The ratio between boys and girls in each group was two to one for mongols and imbeciles, four to one for idiots, and eight to one for disturbed children. With such small numbers the high ratio for disturbed children can only be suggestive; the other ratios are similar to those usually found. The I.Q.s, I.Q. range, average ages, and age ranges of the various groups are given in Table II.

TABLE II.—I.Q. and Age of Four Groups of Children Awaiting Admission

Group	No.	I.Q.		Age in Years	
		Average	Range	Average	Range
Disturbed	9	31	17-49	4.25	2.42-5.67
Idiots	20	7	2-16	2.75	1-5.08
Imbeciles	9	30	25-40	2.83	1.75-4.5
Mongols	12	45	13-84	2.33	0.25-7
Total	50	25	2-84	2.92	0.25-7

Of the 50 children tested in this group 12 were mongols, 20 were low-grade idiots, and 9 were imbeciles. These groups showed no marked behaviour problems; however, the nine remaining children showed severe emotional symptoms. The behaviour of these disturbed children might be due to brain damage, psychosis, emotional disturbance, or deafness, or any combination of these. They appeared to be physically fairly normal, although a little undersized. Their behaviour was characterized by restlessness, mannerisms, screaming attacks, perseveration, and avoidance of contact with people, although they sometimes made contact with their parents. The histories of these nine children were investigated, and in three cases there had been a disturbed background, early separation, or neglect, but in the other six there was no obvious explanation; the child had been at home with apparently well-adjusted parents and had normal siblings. It was decided to assess the backgrounds of the remaining children. Each child was considered in alphabetical order and put into one of two groups: those who had been separated from their mother for over three months, who had been abandoned, or whose parents showed signs of neurosis were described as having an abnormal background, while those who had spent all their lives in a stable home were described as having a normal background. The results are given in Table III. It will be seen that the homes of the disturbed children are no less stable than the others.

TABLE III.—Number of Children Coming from Normal and Abnormal Homes in Each Group

Group	No.	Normal Home	Abnormal Home
Disturbed	9	6	3
Idiots	20	13	7
Imbeciles	9	4	5
Mongols	12	6	6
Total	50	29	21

Discussion

It is realized that this division into "normal" and "abnormal" is rather arbitrary, that there may be hidden factors which have been overlooked, and that in some cases the child's original deficiency may have caused the abandonment, long hospitalization, etc.; however, nearly half the children in this group have had enough in their upbringing to justify disturbance, and the disturbed children's background does not appear to differ from the others. This was contrary to what was expected, and might be due to the smallness of the numbers, or the disturbed behaviour being caused by other than environmental factors. This does not detract from the possibility of individual children functioning on a defective level for no other reasons than emotional ones.

The high incidence of children with disturbed backgrounds is due to this group being selected because, for the various

I.Q. scatter of children awaiting admission to a mental deficiency hospital.

reasons given above, their parents felt it best for them to come into hospital care. However, nearly all the parents seen wished strongly that they could have managed to keep their child at home.

The further study of differences between behaviour at home and behaviour in a new environment such as a hospital may prove of use in distinguishing the components of this probably mixed group who show disturbed behaviour.

The earlier home visit was found to be useful for several reasons. Firstly, to give the parents the opportunity of discussing their individual anxieties about the hospital with the hospital social worker. These anxieties are very varied, and include advice on allowance, delays in admission, emergency provisions, visiting arrangements, sick-notice procedure, availability of medical advice, legal implications, clothing, and provision of toys, as well as the child's future placement. In some cases the parents are not sure whether they want a vacancy, and wish to discuss this with the hospital social worker in order to clarify their ideas on hospital care.

Secondly, the visit was useful to correct any serious misunderstanding regarding the child and his hospital treatment. As patients naturally wish their child to be "cured" and some hope for curative treatment, it is necessary to explain to them that, although research is being carried out, as yet it is unwise to expect any cure. It is important to correct misconceptions such as that mongols usually die at 5 years of age and that the children are kept permanently in bed. Before visiting the hospital the parents may not realize the essential differences between this hospital and one for general medical treatment. With increasing awareness of mental deficiency in society, it is now rare for the parents to confuse mental illness with mental deficiency, but when this occurs it is important to clarify the position before the child is admitted.

Thirdly, at this home visit an out-patient appointment can be suggested, and this provides an opportunity for the parents to consult a specialist and see the hospital, and for the child to have a pre-admission assessment by a psychologist. This psychological test is useful as an early record and for research purposes. It also affords an opportunity for eliminating educable children from the waiting-list; it has been found that they are more likely to succeed if they go straight to school instead of having to adjust to an initial period of hospital care.

Lastly, an earlier visit is useful in making known the specialized services and experience of the hospital. These include arranging friendly contact between parents of waiting-list children and parents of those already admitted, and giving general advice on training and feeding when requested. Some of the parents felt that their normal home care for the child might be inadequate; one parent was very worried because, despite the fact that her child had a good set of teeth, she could not teach him to chew, not realizing that this was quite usual. Most of the parents were aware of the provision of temporary care, but wanted to know exact details from someone working in the hospital.

There was a discrepancy from area to area in the ways in which parents had been helped. Where statutory supervision is carried out by trained social workers the parents appeared to be more adequately informed of the implications of hospital care. Nevertheless there was still a need for a direct personal contact between the hospital and the parents. This would almost certainly lead to closer co-operation in future years.

In spite of the advantages of an earlier visit a difficulty is presented by the fact that out of the 100 consecutive cases 50 were withdrawn for various reasons. Nevertheless it is considered that the earlier visit would help the parents to adjust to the various problems relating to having a defective child. Likewise, the pre-admission testing by a psychologist would be found most valuable, not only in assessing the child's abilities but also in observing his behaviour in relation to his parents.

Summary

One hundred consecutive cases awaiting admission to a mental deficiency hospital for children were investigated. Joint home visits by a social worker and psychologist were paid to find the factors precipitating the request for admission, to test the child's intelligence, and to assess the usefulness of an earlier home visit by the social worker. In spite of the extra time involved, the value of an earlier visit was thought to be considerable. The children were found to divide into four categories, their I.Q.'s and age ranges are given, and a review was made of their home background. Out-patient visits to the hospital for examination and psychological testing are recommended, with home testing only in special circumstances.

ISRAEL MEDICAL ASSOCIATION

FOURTH WORLD ASSEMBLY

[FROM A SPECIAL CORRESPONDENT]

The Israel Medical Association held its fourth world assembly at Tel Aviv from August 12 to 24, under the chairmanship of Dr. J. BICKELS. Great Britain was represented by Dr. E. E. LIEBER. The inaugural ceremony was attended by both the Prime Minister of Israel and the Minister of Health. Dr. S. WAND, Chairman of Council of the B.M.A., attended the last two days of the meeting, and was made an honorary member of the Assembly.

Professor Zondek's Address

Welcoming the overseas delegates, Professor HERMAN ZONDEK said that, though they might see in Israel problems and disease entities bearing the stamp of local climatic, nutritional, and social conditions, it would be absurd to speak of a national or specifically Jewish medicine. There was, however, an intimate connexion between the teaching of Judaism and the ethical aspects of medicine. The *Old Testament* message, Man is made in the image of God, imposed for the first time the moral obligation to respect the sanctity of life, a postulate that formed the ethical foundation of their profession. In the spirit of this tradition Jews had always shown a marked affinity to medicine, and for centuries this attitude had been instrumental in leading a disproportionately great number of Jews to the study of the natural sciences and to the medical profession.

Professor Zondek then turned to the scientific aspects of medicine. What had been their contribution to the philosophy underlying the profession of medicine? Not so long ago scientific thought had been largely dominated by the mechanistic doctrine of causality, reflected in such trends as rationalism, materialism, Darwinism, naturalism, and so on, until the human organism had been converted into a soulless machine. However, deeper insight into the workings of Nature had given a new direction to natural philosophical thought. In their lifetimes they had been privileged to witness the enormous strides made by the physical sciences, and not least by medicine; and yet they had not come a single step nearer to solving the essential riddle of life. Some examples from his own field of research would illustrate what he meant. "When I was a young assistant at the Charité in Berlin, nearly fifty years ago," said Professor Zondek, "the question cropped up whether the ganglia of the heart were responsible for the movement of the heart muscle or whether the latter possessed an inherent capacity for its activity as advocated by Ludwig and my teacher His. I still remember the crucial experiment which, at the time, roused much comment. A small piece of embryonic chicken

part, certainly devoid of nerve substance, was put into a test-tube and suspended in Carrel's solution. After a while it began to contract in the rhythm of the normal heart beat." The cause of the alternating contraction and relaxation which the heart relentlessly keeps up for decades was thus inherent in the heart muscle. Yet the eternal question stood, Why does a piece of tissue spontaneously start functioning at a given moment to stop without apparent cause?

The physician of our time, no matter to which school of thought he might adhere, was called upon to take a greater part in public life than hitherto. Humanity in our time was sick, suffering from numerous endogenous ailments—moral, political, and economic threats to its very existence—the most dangerous of which was the unchaining of atomic power. Humanity would no more get rid of that great threat. It seemed easy to die with the atomic bomb, but how should one live with it? Medicine was at a loss to devise a remedy, but doctors could contribute by an educational effort to increase respect and reverence for the miracle and sanctity of organic life.

Selected Scientific Papers

The second day was devoted to various papers on health progress in Israel. Despite the immense difficulties, during the 10 years of its existence the State of Israel has achieved remarkable results in the various fields of health, which are reflected in the country's vital statistics. The birth rate is high (28) but the death rate low (6.3); infant mortality at 32 is only a fraction of that in most countries in the Middle East; life expectancy (68) is comparable with that in the U.S.A. (72), and the mortality rate from tuberculosis (7.1) is the second lowest in the world.

There was a symposium on blood diseases. Dr. Y. MATOTH said a high incidence of thalassaemia had been found among Jews from Kurdistan. Over a five-year period 80 new cases of thalassaemia had been diagnosed among Kurdish children and adults in the Jerusalem area, including 11 new cases of thalassaemia major, the homozygous state. The frequency of thalassaemia in this Kurdish population had been calculated as 0.0663 for the homozygous state and 0.123 for the heterozygous state. Rare instances of thalassaemia had been encountered among Jews from other Middle Eastern regions, but an extensive search for abnormal haemoglobins by paper electrophoresis among members of various other Jewish communities had yielded negative results. It seemed, therefore, that thalassaemia was the result of only haemoglobinopathy affecting Jews in Israel, and that it was virtually limited to those from Kurdistan. Dr. C. SHEBA said that haemolytic reactions to sulpha drugs and other noxious agents occurred only among the non-European Jews. The erythrocytes of those who had suffered from such reactions showed a low glutathione concentration, glutathione instability, defective glucose-6-phosphate-dihydrogenase activity, and a low rate of incorporation of radioactive glycine into glutathione. In a survey of 2,000 control subjects, no such abnormalities were found among European Jews, while 10% of the non-European Jews were affected. The abnormality was most frequent among those originating from Iraq (about 20%); in other groups studied (Yemenites or immigrants from North Africa) the frequency was about 5%. In Italy this trait is found only in subjects of Sardinian and Sicilian origin. Genetic evaluation showed the abnormal trait to be sex-linked, incompletely dominant, with sex-conditioned variable expressivity.

Dr. D. BRUNER spoke on myocardial infarction in Yemenite Jews. Conditions in Israel presented an excellent opportunity for studying the aetiology of atherosclerotic heart disease and the relationship between lipid patterns and the incidence of coronary disease. The very large immigrant population of European Jews had a high incidence of coronary disease as in the Western world, while the Yemenite Jews were practically free from atherosclerotic heart disease and angina pectoris in middle age. An analysis of the various lipid fractions in 74 patients with myocardial

infarction showed that in only 10.8% of them was the β -cholesterol level less than 180 mg./100 ml. On the other hand none of 32 Yemenite farmers had a β -cholesterol level over 180. Despite a low total cholesterol among the Yemenites, α -cholesterol levels were very similar in both the European (healthy and affected) and the Yemenite groups studied.

Dr. E. E. LIEBER (Great Britain) described an inquiry into whether certain industrial dusts and vapours in a factory could cause chest disease. The dusts contained glass monofilaments, beryllium-copper alloy, epoxy resins, and polyesters. He regarded the occasional case of emphysema as the result of the action of polyester and epoxy resin dusts on the pulmonary neurovascular tissue. Lung markings caused by polyester dust were due purely to its mechanical irritant effect, not to any chemical toxic reaction. The prognosis in all cases was excellent, and the patient's condition did not continue to deteriorate after removal from exposure. Normal dust extraction equipment plus the usual additional prophylactic measures were adequate to protect workers engaged in handling glass fibres or epoxy resins in any form.

Professor A. DE VRIES gave the results of an epidemiological investigation of urolithiasis in Israel. In 12 settlements, selected because of different climate and ethnic composition, the incidence was high. In males the incidence was 14.4% and in females 8.8%. The incidence was highest in the hottest and lowest in the coolest regions, higher in immigrants from Europe than in those from the Middle East and North Africa, low in those born in Israel and in immigrants below the age of 18, though in the latter it rose sharply after that age. In the large majority of the patients the urolithiasis developed within the first five years of arrival in Israel. Inadequate fluid intake was the most satisfactory explanation of these findings. Ethnic differences could be explained by differences in drinking habits.

PROMOTION OF THE SALE OF DRUGS AMERICAN CODE

The two main associations of drug manufacturers in the U.S.A.—the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association—have recently merged. The newly formed organization is called the Pharmaceutical Manufacturers' Association, and one of its first actions was to issue the following statement of principles¹ applying to the promotion of pharmaceutical products sold only to the medical and allied professions:

"We, members of the Pharmaceutical Manufacturers' Association, recognizing our responsibilities and obligations to promote the public welfare and to maintain honourable, fair and friendly relations with the medical profession, with associated sciences, and with the public, do pledge ourselves to the following statement of principles:

"(1) Prompt, complete, conservative and accurate information concerning therapeutic agents shall be made available to the medical profession.

"(2) Any statement involved in product promotional communications must be supported by adequate and acceptable scientific evidence. Claims must not be stronger than such evidence warrants. Every effort must be made to avoid ambiguity and implied endorsement. Whenever market, statistical, or background information or references to unpublished literature or observations are used in promotional literature, the source must be available to the physician upon request.

"(3) Quotations from the medical literature or from the personal communications of clinical investigators in promotional communications must not change or distort the true meaning of the author.

"(4) If it is necessary to include comparisons of drugs in promotional communications, such comparisons must be

¹ *Drug Trade News*, June 2, 1958.

used only when they are constructive to the physician and made on a sound, professional and factual basis. Trade-marks are private property that can be used legally only by or with the consent of owners of trademarks.

"(5) The release to the lay public of information on the clinical use of a new drug or to a new use of an established drug prior to adequate acceptance and presentation to the medical profession is not in the best interests of the medical profession or the layman.

"(6) All medical claims and assertions contained in promotional communications should have medical review prior to their release.

"(7) Any violation of these principles brought to the attention of the president of the Pharmaceutical Manufacturers' Association shall be referred by him to the Board of Directors."

MEDICAL DEFENCE UNION

The 73rd annual meeting of the Medical Defence Union was held this year at the Royal Victoria Infirmary, Newcastle upon Tyne. It took place on September 16, under the chairmanship of Dr. S. COCHRANE SHANKS, president of the Union, who presented the annual report. The total membership at July 15 was 45,374, of whom 8,182 were women and 3,258 life members. During 1957 the Union handled 2,492 cases, compared with 2,379 the year before. The accounts, which were presented by Dr. HENRY ROBINSON, showed an adverse balance of £19,241, owing to generally rising costs and the rise in indemnity claims (over £33,000). The subscription had had to be raised on May 1 from £2 to £3 per annum, but this sum was eligible for tax relief under the Finance Act, 1958, as a necessary expense, making the net amount now no more than 34s. 6d.

Hazards of Practice

Mr. A. HEDLEY WHYTE, senior surgeon to the Royal Victoria Infirmary, gave the customary address, choosing as his subject for his largely student audience "The Hazards of Practice." After relating a number of the commoner disasters and one unusual one in which recently a pathologist was asked to examine a specimen of duodenum obtained by sigmoidoscopy, Mr. Hedley Whyte described some of the precautions currently in force at the Infirmary. In particular he described the rigorous safeguards adopted routinely against any chance of the surgeon operating on the wrong patient, or a wrong part of him, of swabs or other objects being left behind in body cavities, of incompatible blood transfusion, and against tetanus.

In the theatre three kinds of swab were used—packs, mops, and stamp gauzes. Stamp gauzes were always on holders and never loose. Packs and mops were of the "raytex" variety, marked with a thin radio-opaque line. These swabs were counted, before sterilization, into bundles tied in fives, counted out again before operation, and the number in use chalked on a board for all to see. Before the beginning of wound closure the swab count, clip and needle counts, must all be correct, and similarly a second correct count must be agreed before the patient left the theatre. They thought this the best method, and had no use for tapes or similar contraptions tied to swabs.

The problem of tetanus was not so satisfactory, although the outcome was less gloomy than heretofore. Cases still occurred, however, at the rate of two or three a year. At the Royal Victoria Infirmary all patients were given some sort of prophylactic treatment, irrespective of the site of the wound, whether or not it was penetrating, or the likelihood of its being contaminated. No case was missed, so vigilant was this service. Usually the patient was given a divided dose of 1,500 units of A.T.S. in 1 ml. First the patient was questioned about his susceptibility to various foods and about asthma or hay-fever, and then given 0.2 ml. of A.T.S., and after 20 minutes the remaining 0.8 ml. If there was any possibility of sensitivity, then a minute intradermal dose was tried, and if there was no untoward reaction then the

(Continued at foot of next column)

To-day's Drugs

In this column we publish from time to time authoritative notes on a selection of drugs in current use.

Uniplex (Weddel Pharmaceuticals, Division of the Union International Co. Ltd.). Each tablet contains 125 mg. of granulated whole liver extract, 1 mg. aneurine hydrochloride, 1 mg. riboflavine, and 5 mg. nicotinamide. Uniplex is intended for treating such conditions as pyrexia, debility, neuritis, glossitis, diabetes, pregnancy, lactation, or impaired function of kidney or liver in which the intake of vitamin B may be below normal.

Deficiency symptoms of vitamin-B complex vary considerably, since it is concerned with general metabolism, and all types of tissue may be affected. When symptoms are due to a deficiency of it, a satisfactory response may be expected on administration of this preparation. Patients who have to live on a restricted diet may also be helped by this product.

N.H.S. basic price: 50 tabs., 2s. 8d.

Ferronicum (Sandoz Products Ltd.).—Each sugar-coated tablet contains ferrous gluconate 300 mg., equivalent to 35 mg. bivalent elemental iron. This preparation is intended for the treatment of iron-deficiency anaemia in doses of 2 tablets three times daily in post-haemorrhagic anaemia, 3-4 tablets three times daily in essential hypochromic anaemia, and for anaemia after gastric resection 4 tablets five times daily; for children up to 12 months 1-2 tablets daily crushed in water, and for older children 3-9 tablets daily. A normal response should be obtained with 3-6 tablets daily. While this is an effective preparation in the treatment of iron-deficiency anaemia, it costs more than ferrous gluconate tablets N.F., which have the same clinical effects.

N.H.S. basic price: 100 tabs., 3s.

Distivit Vitamin B₁₂ Peptide Complex (The Distillers Co. (Biochemicals) Ltd.).—A tablet contains cyanocobalamin (vitamin B₁₂) combined with a peptide to form what is called vitamin B₁₂ peptide complex. Supplied in tablets containing 20 or 100 µg. vitamin B₁₂. This is intended for the oral treatment of pernicious anaemia and similar megaloblastic anaemias as well as subacute combined degeneration of the cord. The treatment recommended is 100 µg. of B₁₂ in the form of this complex three times daily for ten days, followed by 100 µg. daily until the blood count reaches normal levels. Maintenance dose thereafter is adjusted according to the response obtained in the patient.

This is a new preparation, and the follow-up of patients treated with it for pernicious anaemia is not yet adequate to judge its effects fully. A few cases have been reported and have been treated over short periods of time with good results, but other patients have not responded so well. Long-term observations are needed before a full assessment can be made of the value of this treatment in pernicious anaemia, and it would be worth making these.

N.H.S. basic price: 20-µg. tabs., 100 for 8s. 8d.; 100-µg. tabs., 100 for 21s. 10d.

(Continued from preceding column)

remainder was given in 20 minutes. Should a reaction be feared, then toxoid was administered, a second dose being given in two weeks' time. Where it could be ascertained that triple vaccine against diphtheria, whooping-cough, and tetanus had been given in childhood, as was increasingly the case, then a 1 ml. dose of toxoid only was given. During the last five years they had had 14 cases of tetanus, of which seven recovered, although the last two cases had died. It was disturbing that both these last two cases had been treated prophylactically before admission, one at home and the other at another hospital, and both with apparently adequate dosage.

Correspondence

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Medical Education

SIR, I very much welcomed the article of Dr. Richard Scott (*Journal*, September 6, p. 577) and the report of the College of General Practitioners on psychological medicine (p. 585) in your educational number. I ask myself whether the recommendations made therein are good, and also what response the medical schools should make. Progress in medical education occurs slowly because it is generally envisaged in a fixed framework; the effort to find more room for more subjects is frustrated by the difficulties of omitting or contracting others. There would soon be no progress at all were it not that a less rigid curriculum has increased teaching freedom, and were it not that the faint possibility of change in examination method gives some hope that the mutual neurosis of students and teachers (comparable to the situation of 11-plus) might be eased.

The demands made in these two articles are, firstly from Dr. Scott, that students should see general practice for two weeks at a late date in their training, and after his analysis of the defects of medical teaching in hospitals the conclusion is to me *ridiculus mus*. The College of General Practitioners' report requires greater emphasis on normal psychology and psychological medicine, a compulsory question on these subjects in the final examination (I view with deep fear and depression: "What are the indications for E.C.T.?"), but, fearing the inadequacy of these suggestions, a demand also for more postgraduate education. I am full of sympathy, but think that these demands should be much more radical and courageous. If, as Dr. Scott says, the diagnostic method of the general practitioner involves a synthesis of all factors, whereas the hospital method is analytical and exclusive of data, then if the former is right the latter should be brought into line. If, as the College suggests, 30% of all morbidity seen by practitioners is due to mental stress, etc., then too we must adapt our teaching to meet this.

We will fail to correct our teaching until we recognize that medicine must be a study of all aspects of man as he lives in society. Social medicine, psychological medicine, or organic medicine are all useful but misleading isolates from the whole complex, and each tends by itself to give a distorted view. Six complex, and each tends by itself to give a distorted view. Six years are spent in undergraduate medical education; for two and a half to three years man is cut into pieces in studies of anatomy, physiology, and biochemistry, and towards the end of the period there may be some lectures on man's behaviour. These isolates are never integrated, and man (*Homo sapiens*—such is our conceit) has been dissected with a scalpel, microscope, a chemical balance, etc. The student, thinking that when he enters his clinical years he will meet people, comes up against an introductory course which should tell him that all these dull things he has learnt and is trying so hard to forget are his basic sciences, and the process of integration which should commence is progressively swamped by fact-cramming—but of course he is considered to be too immature for psychological medicine. The eclectic psychiatrists sometimes pooh-pooh the Id and the Ego and the Freudian heresy, and belabour the student with taxonomy, fear of transference situations (our old friend the doctor-patient relationship). Why can't the student be taught about his own mental maturation, his own adjustment to society from birth onward, so that he himself can mature more rapidly and become a real doctor?

It is a pity that the term "psychosomatic" is so useful for a limited group of disorders, for indeed all medicine is psychosomatic and each individual's psyche develops in his ever-changing social setting. Can we not begin our clinical studies with this in mind? Many physicians have found insufficient help from their psychiatric colleagues in their everyday work; they envy their American colleagues who have fully staffed psychotherapy departments available. So they are now forced, perhaps fortunately, to learn about this large aspect of their patients. Can we not now teach our students from the commencement of their clinical work that a case history is not a record of symptoms, plus a few

isolated data about family and social setting, but a history of a person and how it is to be understood? Let the student find out why Mr. A. visits the pub and puts off his evening return to his termagant wife, find out why Mrs. A. is a termagant wife; and to understand why Mrs. B. is ill, she being a rejected but still matriarchal mother-in-law; why Mr. C., middle-aged, is unmarried, hypertensive, and still living with his parents. If such is the setting of so much illness (*vide* H. G. Wolff, *Lancet*, 1958, 2, 206) much of the teaching should be done by the physician, who will need help, but the important thing is to keep the student in this human atmosphere for eighteen months in medical, surgical, paediatric, and gynaecological departments only: the surgeon too must teach him about people, their fears of pain and surgery, the loss of employment, the full meaning of rehabilitation; the paediatrician must teach about mothers and fathers, affection, security, and the lack of these; the gynaecologist must teach about women, and that if menstrual upsets are caused by stress psychological methods should be used, teach too what a womb means to a woman and what threatened womblessness portends. Of course the student must learn too that estimations of electrolytes, surgical procedures, isotopes, etc., are also instruments for the investigation of or treatment of a sick human being. Quite early he must learn to talk to patients—learn what to say and ask, learn how to listen with every faculty alert, and to interpret the verbal and other communications with patients, understand too what people feel like when distended with barium enemas in dark rooms, or sigmoidoscoped with bottoms exposed. What shocking examples so many of us set in our rounds, how little we know what a frantic hour ward sisters spend soothing patients, answering their questions—What did HE say? What did HE mean? The busy teaching physician must educate his staff because the eager registrar is often cynical behind his back; perhaps they should not be promoted until they have had a dose of Dr. Balint or a near equivalent from some of his enthusiastic pupils who have been so actively spreading the light.

I have only sketched an approach. I have said nothing new, there is much agreement, but the working out is very urgent before the distended curriculum bursts.—I am, etc.,

London, W.1.

HUGH GAINSBOROUGH.

SIR,—The educational number of the *Journal* (September 6) and the report of the College of General Practitioners' working party on psychological medicine in general practice (*Journal*, September 6, p. 585) raise important issues.

Pre-registration Training.—I believe that this is unnecessarily protracted by one year by virtue of an over-academic preclinical course. To give but one example, 18 months are spent learning anatomy in fine detail, soon to be forgotten. The acquisition of such knowledge is the concern of the postgraduate budding anatomist or surgeon, etc. The fundamentals, which can be learnt in half the time, are adequate for the general practitioner. During clinical training, emphasis is still centred on disease *per se*. The revelation now to me is that what matters more is the patient's mental manipulation of his disease and environment—including his medical advisers—and the varying degree of ego breakdown, with its concomitant somatic effects, in different persons affected by a similar aetiological agent. In addition to teaching normal and abnormal psychology as such, their participation in every branch of medicine must be impressed upon students, so that from the outset they have a deeper insight into their patients' problems. Now that at least a third of disease has been assigned to the realm of psychopathology, the suggested inclusion of one compulsory psychiatric question in finals (marked, we hope, by the "interested" examiner) is conservatively timid. There should of course be both a written and an oral examination. The introduction of the pre-registration year, to be served in hospital, is an impertinence to the qualified doctor. It serves no intrinsic value and should be abolished.

Post-registration Study.—The plea for improved training facilities for the general practitioner is well founded. Part-time courses with adequate instruction for higher qualifications in all branches are also necessary. Lack of available time and lack of pecuniary reward for doing specialized work in the N.H.S. are difficulties which could be met by a reduction in list size with commensurate financial compensation.

I disagree with the working party's opinion that the use of hypnosis is, "at present, outside the normal province of general practice." I find it of real value. For example, when symptom-removal by direct suggestion is employed, say in so-called psychogenic rheumatism, it compares favourably with the hospital physiotherapy department as a faith-healing agent, and time, expense, and manpower are saved. Although much is unknown about hypnosis, the fact remains that its lay use is increasing. Rather than dismiss it arbitrarily, the wise course would be to establish a university department for its scientific study and appraisal.

In the National Health Service of the future the role of the general practitioner will increasingly become that of an intermediary whose duties could be largely performed by a civil servant, unless the doctor is given the opportunity to establish his legitimate position as a person of education and authority in that particular branch of general practice in which he has special interest.—I am, etc.,

Edmonton, N.9.

HAROLD FOX.

Contraception by Inhibition of Ovulation

SIR,—Dr. B. H. Kirman (*Journal*, August 30, p. 565) criticizes my annotation (*Journal*, August 2, p. 297) on the use of "enavid" as an oral contraceptive. His criticisms are based on several misconceptions. Firstly, he compares the toxicity of progesterone, a naturally occurring hormone, with that of aminopterin, a known tissue poison, whose effect upon fertility may well include an abortifacient action mediated by its toxic effect upon the foetus. It is quite misleading to compare the toxic action of aminopterin with the very occasional report of foetal abnormalities following progesterone and other progestational agents. In any case his fears are, I believe, groundless, as the design of the Puerto Rican study is such that any patient becoming pregnant would automatically discontinue taking the tablets, and not therefore be exposed to the hypothetical risk to the foetus which might result from continued hormone administration during the early months of pregnancy. Quite apart from this consideration, I would like to point out that foetal malformation has not so far been reported following administration of enavid in pregnancy. (There is a growing experience of such administration in the treatment of recurrent abortion, for which the use of a progestational agent has been suggested by Goldzieher and Benigno.¹) The intrinsic oestrogenic activity of enavid encourages the hope that this drug may prove safer for administration during pregnancy than other progestational agents, many of which, including progesterone itself, show slight androgenic activity in some situations.

Secondly, Dr. Kirman comments that "it is surely unwise to permit the marketing and widespread use of such potent compounds for this purpose" (contraception). If Dr. Kirman is under the impression that enavid is marketed for this purpose, he is under a misapprehension, as this is not the case. The makers have at no time made such a recommendation for its use. In due course the field trial in Puerto Rico will show whether or not long-term use of this method of contraception is safe. Thirdly, Dr. Kirman criticizes the choice of Puerto Rico for the site of the trial. The choice was in fact a good one for several reasons. The population problem in Puerto Rico is such that there is a strongly felt need for a reliable method of contraception. There was already a useful background knowledge of the fertility of the population to be studied. The fact that the previous pregnancy rate was a high one rendered the population particularly suitable for this type of field trial.

I would agree entirely with your annotation that even at this early stage (third year) of a long-term scientific study "a remarkable step forward" has been made.—I am, etc.,

High Wycombe, Bucks.

Anaesthetic Hazards

SIR,—The occupational hazards of an anaesthetist include those of drug addiction, unhappily more common, I believe, than generally recognized. Adopting the methods recommended by Dr. Victor Goldman (*Journal*, August 2, p. 327) of not only smelling, not only sniffing, but testing by the administrator everything it is intended to use on the patient, would seem to add greatly to the risks referred to above. Addition to nitrous oxide/oxygen, nitrous oxide/air, not to mention the more potent inhalational agents, would seem to be encouraged by this. Surely safety is ensured by careful checking of cylinders, connexions, and bottle contents. I am, etc.,

Plymouth.

R. E. ANGEL.

Antenatal Irradiation and Childhood Malignancies

SIR,—The fact that the authors of the investigation into childhood malignancies¹ have now stated that antenatal x-rays cannot account for the apparent rise in infantile cancer will be welcomed by all x-ray workers. This conclusion does not, however, go far enough in dispelling the impression created and spread by the lay press that diagnostic x-ray examinations are dangerous and harmful. The investigators themselves are convinced that they proved beyond all reasonable doubt that there exists a causal relationship between antenatal diagnostic irradiation and malignancy, and in this they seem to be supported by an irrefutable set of figures. If their results were accepted it would mean that one child of every 3,000 mothers who had a pregnancy x-ray would develop cancer and that between 20 and 30 cases of childhood cancer out of a total of 500 cases a year might be directly attributable to antenatal irradiation.

The publication of their preliminary report² has resulted in antenatal x-ray examinations being severely curtailed by obstetricians and radiologists. It can only be a guess that the lack of x-ray confirmation of various maternal or foetal conditions may maintain the high maternal death rate (399 in 1956), the stillbirth rate (16,505), and the neonatal death rate (11,779). If one assumes that with adequate x-ray surveys of the pregnant population only as little as 1% of these mothers and babies could be saved, this would give us over 10 times as many live births as dead babies from a possible malignancy in childhood, not to mention fewer feeble-minded and spastic children following birth injuries. In spite of the apparent smallness of the risk attached to such examinations, I still feel it necessary to remove the stigma which has been attached to such x-ray procedures for the past two years since the publication of the preliminary report.

I analysed the figures of my own x-ray examinations on pregnant women during the past 15 years and found among 4,000 cases x-rayed in one hospital in Hertfordshire no case of childhood leukaemia, but there were six cases of leukaemia in children of non-irradiated mothers. A rough check on a further 3,000 cases from a London maternity hospital did not reveal a post-radiation leukaemia either. I am fully aware that my own figures are not statistically important, but they still suggest that the problem should be critically re-examined in case there is a flaw in the investigations which in itself would account for the unusual and unexpected result of their survey.

In my opinion the authors¹ have not paid enough attention to the various groups of maternal characteristics which differ widely in their respective numbers in the case and control groups and which may constitute an increased indication for the taking of radiographs. The authors set out to prove that a certain factor had been induced in the foetus during intrauterine life which would eventually develop into a malignant condition. Therefore not only the children but also the maternal state before and during pregnancy should have been closely matched in the two groups. The total differences in numbers of irradiated women between the case and control groups (their Table VII) amounts to 60 for a three-year period. If it can be proved that these 60 cases can be accounted for by differences in the two

groups of mothers, then the results of this survey would become very questionable.

(1) Primigravidae in the survey amounted to 510 in the case group, against only 427 controls with 8.4% of the latter x-rayed. The rate of multiparae (with at least two previous births) x-rayed is given as 6.8%. But such a percentage difference cannot occur in a normal control group, as every x-ray department will examine at least twice as many primigravidae as multiparae. (My own figures: 1957, 2.6 : 1; 1958, so far, as 2.5 : 1). The only explanation for the authors' ratio (8.4% : 6.8% = 1.2 : 1) can lie in considerable under-reporting of the controls—i.e., one mother in 40 failed to record an antenatal x-ray. If we assume that the percentage of primigravidae x-rayed was twice that of multiparae, then we arrive at 13.6% for 510 primigravidae = 69 cases. This would give 33 more cases than those recorded, and it would reduce the differential between the case and control group to less than 30.

(2) Elderly mothers are much more frequently x-rayed than a young mother. I believe that there were a total of 67 women over 40 years in the case group, and, in the absence of figures supplied, I assume that over 30 of these were surplus over the control group.

(3) Mothers' illnesses during pregnancy fall into two groups: (a) *Infectious diseases*, of which an excess of 12 was found in the neoplastic group, and (b) *diseases specifically associated with pregnancy*: toxæmias, genito-urinary infections, and threatened abortions, which showed a surplus of 36 on the case side. It is obvious that if 48 extra cases of similar illnesses were included on the control side then the number of x-ray cases would go up considerably in this group.

(4) Mothers' past histories disclose an excess of 37 case mothers with a total of 48 abortions and a further seven case mothers with a history of at least one stillborn child. Here again the clinician will order more x-ray examinations than in a group of normal patients.

Altogether the last three groups show an excess of 122 anomalous mothers in the case group, each one of whom is a more likely subject for an x-ray examination than a normal pregnancy case. If a corresponding number of 122 abnormal women were included on the control side with the object of making both groups reasonably equal then we could expect that at least one in four of these anomalous types would be referred for an x-ray examination. This would reduce the difference between the two groups to zero and would have the following results: (1) The whole argument that antenatal x-rays in small doses can be responsible for childhood malignancies becomes null and void. (2) It would throw doubt upon the widely held belief that human foetal cells are more susceptible to x-radiation than adult cells. (3) It would confirm the view that a fairly high threshold dose exists below which x-rays are harmless.—I am, etc.,

Sweet Tooth and Decay

SIR, In your issue of September 6 (p. 638) is printed a letter by Mr. F. T. Ranson that calls for early reply. He argues that sugar does not seem likely to be the cause of dental decay, since the chewing of sugar-cane in Jamaica appears to be a powerful preventer of decay. After three years in Trinidad during the war I would accept the latter fact without hesitation, but the reason is that sugar-cane is a natural material. Not only is the fibre in the sugar-cane addition any cane cells left lying around the teeth afterwards are still alive and so the antibodies in these cells prevent bacteria attacking them, just as our own do as long as we are alive. In both these respects the unnatural sweetmeats and other contents of confectionery shops present a most striking and tragic contrast.—I am, etc.,

Gosport, Hants.

T. L. CLEAVE.

SIR,—Having read your article "Sweet Tooth and Decay" (*Journal*, August 2, p. 293) and the interesting point raised later by Mr. F. T. Ranson (*Journal*, September 6, p. 638) that "chewing sugar-cane and good teeth go together," may

I say that there is some truth in that statement? The fact is that it is not only due to sugar-cane that the West Indians have such excellent teeth—not forgetting the sunshine for a moment—it is the chewing of hard food that gives exercise to the muscles of the jaw, thereby promoting better circulation, consequently denser calcification and dentition and glossy enamelling. We must not forget that Asiatics and African races not only avoid soft sloppy feeding but clean their teeth with religious scruple, not leaving any bacteria to flourish and cause havoc. Medical men and especially dental surgeons hope that the habit of oral hygiene will be inculcated in schoolchildren all over the world.—I am, etc.,

Abbots Langley, Herts.

A. K. K. NYAZAI.

Fishbone Furunculosis

SIR,—During the late summer months at Lowestoft and Llandudno I have seen a number of cases of a skin eruption which occurs amongst fishermen. Following a fishbone scratch (apparently irrespective of the type of fish) small furuncles crop up on the fingers. They resemble normal furuncles but are not so painful and there is no lymphadenopathy. *Staphylococcus aureus* has been grown from the yellow discharge. The condition rapidly responds to intramuscular penicillin. The local fishermen say the condition is common amongst them, but only during the months of August and September. I would be interested to hear of any further cases.—I am, etc.,

Llandudno.

PETER COOK.

Premonition of Death

SIR,—On paying my usual routine visit one Tuesday afternoon to a male patient of mine dying from cancer of the lung, the patient took hold of my hands, thanked me for all my attention, and then proceeded to tell me that I would not need to call and see him after Thursday, as he was going to die at 2.30 that afternoon. Needless to say, I comforted him the best way I could, told him to exclude such thoughts from his mind, and promised to look in again.

On late Thursday afternoon I received a message from a member of his family that their father had passed away peacefully. A few days later two daughters of the deceased came to consult me, and in the course of our conversation told me that the day before their father died he had summoned all the members of the family together and repeated to them what he had told me—namely, that he would die the following day at 2.30. On the predicted day, all the members of his family were with him in his bedroom except his wife. As 2.30 was approaching he urgently called for his wife to come in, saying, "Hurry, hurry, before it is too late." She came running into the room, and on the stroke of 2.30, according to the two daughters, "He sighed, raised both hands behind his head, smiled, and passed away." I wonder if any of my colleagues have had a similar experience.—I am, etc.,

Glasgow, S.W.3.

ARNOLD B. COWAN.

Human Factor in Diagnosis

SIR,—I found the article by Dr. C. P. E. Elliott-Binns on the human factor as a cause of delay in diagnosis in general practice (*Journal*, August 2, p. 271) very interesting. I am sure every general practitioner who has been in practice for some time will say to himself after reading it, "Well, I am not the only one who has missed a diagnosis." I think the following type of case is common enough and comes within the third criterion that Dr. Elliott-Binns mentions. In this particular type of case the doctor, after a thorough examination, knows there is something wrong but cannot find the cause. He refers the patient to hospital, where he is investigated as an in- or out-patient, a diagnosis is made, treatment suggested or carried out, and the patient is sent home. Somehow the general practitioner is not happy about the patient's progress, and there are further admissions or attendances at the hospital. The

doctor is none the wiser and begins to think that the patient is either a hypochondriac or a hysteric. Then something turns up and to his horror the doctor finds his patient is suffering from an inoperable condition which is going to prove fatal.

In my view these types of case are here to stay, no matter what one does. But the moral of them surely is that reference of a patient to hospital does not entirely absolve the general practitioner from diagnostic responsibility nor does it relieve his mind from worry when he views the case in retrospect.—I am, etc.,

Liverpool, 18.

H. J. PRATAP.

SIR,—I have been very interested by the article by Dr. C. P. E. Elliott-Binns (*Journal*, August 2, p. 271) and the letter from Dr. M. H. S. Bound (*Journal*, August 23, p. 512) on the human factor in diagnosis. Any doctor of experience can bear out how unpleasant, not to say sometimes fatal, results are due to this factor. They are the recognized penalties of snap diagnosis, and such events, as pointed out, may well inculcate a spirit of humility. While we bewail our insufficiency, however, may we not take comfort from the fact that the number of such accidents and fatalities fades into insignificance when compared with those originating from the same factor in industry and on the roads. On the credit side, also, must be placed the many happy hits of snap diagnosis. Most of us can recall moments when a sort of second sight came to our aid. This, too, may surely be regarded as a human factor, and one which contributes not seldom to important scientific discovery as well as helping to lighten and brighten the multifarious perplexities of our profession.—I am, etc.,

Bristol.

P. T. MACDONALD.

Cord Round the Neck

SIR,—The cases from the literature of multiple loops of umbilical cord around the neck quoted by Dr. H. E. Reiss (*Journal*, June 14, p. 1394) recalled to my mind a case I attended in 1955. As there appears to be no comparable case among those he has quoted, I considered that this information is worth recording. The patient was a primigravida who came into labour at term. A male child weighing 6 lb. 8 oz. (3 kg.) presented with six loops of cord around the neck. The loops were easily removed over the head without cutting, and at no stage was there any evidence of foetal distress. The length of the cord was not measured, but it was, of course, extremely long.—I am, etc.,

Hamilton, New Zealand.

R. E. WRIGHT-ST. CLAIR.

Cancer Education

SIR,—I was interested and slightly amused to see that your correspondent Dr. J. Kenworthy Ogden (*Journal*, August 9, p. 389) has resurrected that old controversy concerning the definition of cure in malignant disease. Everybody will agree with him that in order to produce scientific proof of cure a post-mortem examination must be carried out, but not only is it necessary to find evidence of a different cause of death but it is essential to cut and scrutinize serial sections one cell thick from the scalp to the soles of the feet, a somewhat lengthy undertaking. The same is true for tuberculosis to discover a live tubercle bacillus, and many other diseases. In practice the yardstick of five years' survival without signs or symptoms is very useful.

Dr. Ogden then says it is unwise to instil in the minds of the public that some cancers are "curable" if treated in an early stage, but it is true from the patients' point of view if they get rid of the symptoms and signs and possibly live another twenty years. They are unlikely to worry if a few malignant cells are found post mortem.

Space does not permit me to discuss cancer statistics on which your correspondent touches. He goes on to say he does not object to the public receiving cancer education provided it is based on truth. Truth depends on two people, the person who utters the words, and the person who hears

them. There is no easier way of telling a lie than by telling the exact scientific truth to a lay person who has no scientific training. I wonder what your correspondent would like us to say to the public. Possibly we should say, "If you get cancer you are bound to die even if it is only discovered post mortem many years later." What value would this be to the lay person? The objects of cancer education are to relieve the minds of thousands of people from fear of the disease, and to obtain some more early stage diagnosis, by putting before them a true picture of what can happen if certain cancers (particularly the accessible cancers) are treated in an "early stage." Everybody realizes that the prognosis depends largely on the degree of malignancy of the particular tumour, but unless we revise our ideas about cancer being a progressive disease nobody will deny that the earlier the stage of the disease when the patient is treated the better the prospect of saving life.—I am, etc.,

Oxford.

MALCOLM DONALDSON.

Adrenalectomy and Hypertension

SIR,—Your admirable annotation on "adrenalectomy and hypertension" (*Journal*, August 30, p. 555) could only be criticized as being a little too discouraging about the operation of total adrenalectomy for the malignant phase. If the cardiologists refer such cases for surgery after renal failure has become established the mortality will be prohibitive. However, there are many cases of malignant hypertension which are not yet in renal failure, and if such cases were operated upon as soon as the blood urea, etc., commences to rise the results could be most satisfactory. The blood pressure *per se* is unlikely to be reduced to any marked degree, but the eye changes and the congestive heart changes will be relieved, while the patient's general comfort will be greatly increased.¹ If we exclude the 5 cases of failing renal function from our own series of 13 operations² we are left with 8 patients, all of whom are alive, 1 at six years,³ 3 at four years, 2 at three years, and 2 at over two years. It is interesting that no further deaths have occurred after the second year.—I am, etc.,

London, W.1.

Aetiology of Coronary Disease

SIR,—I read with great interest the article by Professor R. P. Malhotra and Dr. N. S. Pathania on coronary heart disease in their part of India (*Journal*, August 30, p. 528). It is a valuable contribution to our understanding of the disease and I hope may encourage others in India to carry out similar surveys on the differential incidence of disease according to geography and racial habits in that country.

That there is a profound difference in the incidence of the common "Western" diseases of stress, so-called, in different parts of the Indo-Pakistan subcontinent has been very evident for some time. My own field of work has been in East Pakistan and North-east India over 10 years, and I have been intrigued by the difference in incidence, between the north-east and north-west areas of the subcontinent, of the two large disease groups, hypertension and peptic ulcer. Amongst Bengalis, hypertension, and in particular malignant hypertension, seems to be relatively common, though the incidence of the arteriosclerotic conditions fairly rare. Valvular heart disease caused by either rheumatic fever or syphilis is common, but coronary heart disease extremely rare. I cannot recall seeing a single patient complaining of angina of effort, but do remember two cases of coronary thrombosis, both in Muslims of the upper income group, both West Pakistanis, native of an area adjacent to Professor Malhotra's. On the other hand, obliterative arterial disease of the Buerger type is fairly common. It would have been helpful if Professor Malhotra had subdivided his cases in religious groups, as the Sikhs and Hindus have, as he states, differing customs regarding smoking and alcohol, and some difference may have been detected.

I wonder, from his findings and in the light of my own experience, what are the varying influences of diet and mental stress in coronary disease. The Punjabi and Bengali diets differ mainly in the Bengali being a rice-eater while the Punjabi is a wheat-eater.

Apart from that, diet varies according to income and religion. Muslims tend to be meat-eaters to a greater extent than Hindus, many of whom are vegetarians, but a greater amount of fish is eaten than in the West. The main oil used for cooking is mustard oil. Obesity is probably just as common as in the Punjab, but appears to have no relation to causation in our area. I doubt very much if the differences in types of oils used in the two areas can have an influence, but it would perhaps be wise to eliminate this by an analytical study of the various Indian oils before we dismiss the cholesterol content as being irrelevant.

The occupation of the person and his social status may play a very important part. My work was mainly amongst the poorer groups of the population, and it is possible that there may be a higher incidence in Bengali upper-class groups than I have been aware of. However, I do not think that that factor alone is sufficient to account for such a great difference in incidence in the two areas.

Comparisons with colleagues in other parts of Bengal and Assam seem to indicate that the incidence of coronary disease in that area is indeed much lower than in Professor Malhotra's area. What is the answer? I think that the badly neglected study of the epidemiology of diseases such as coronary disease and peptic ulcer in India and Pakistan may throw a great deal of fresh light on these two still very enigmatic "stress" diseases. Diet, customs, and ways of life need to be studied in mass surveys such as have been carried out here in relation to lung carcinoma. Everyone who has lived in India and Pakistan for any length of time knows that the Bengali is by no means a less emotional man than the Punjabi. Why should he not be subject to coronary disease yet be plagued by peptic ulcer?

—I am, etc.,

Eastbourne.

I. T. PATRICK.
